# Chapter 1

## Module Index

### 1.1 Modules

Here is a list of all modules:

OFELI . . . . .	124
Conservation Law Equations . . . . .	17
Electromagnetics . . . . .	19
General Purpose Equations . . . . .	20
Fluid Dynamics . . . . .	25
Laplace equation . . . . .	26
Porous Media problems . . . . .	27
Solid Mechanics . . . . .	28
Heat Transfer . . . . .	29
Input/Output . . . . .	30
Utilities . . . . .	32
Physical properties of media . . . . .	79
Global Variables . . . . .	80
Finite Element Mesh . . . . .	83
Shape Function . . . . .	104
Solver . . . . .	106
Vector and Matrix . . . . .	67

## Chapter 2

# Namespace Index

## 2.1 Namespace List

Here is a list of all documented namespaces with brief descriptions:

OFELI	
A namespace to group all library classes, functions, ..	173

## Chapter 3

# Hierarchical Index

### 3.1 Class Hierarchy

This inheritance list is sorted roughly, but not completely, alphabetically:

BiotSavart . . . . .	205
Domain . . . . .	256
Edge . . . . .	276
EdgeList . . . . .	279
EigenProblemSolver . . . . .	280
Element . . . . .	301
ElementList . . . . .	309
Equa . . . . .	312
Equation< 3, 3, 2, 2 > . . . . .	333
DG . . . . .	242
LaplaceDG2DP1 . . . . .	420
Equation< NEN_, NEE_, NSN_, NSE_ > . . . . .	333
Equa_Electromagnetics< 3, 6, 2, 4 > . . . . .	315
EC2D1T3 . . . . .	270
EC2D2T3 . . . . .	273
HelmholtzBT3 . . . . .	372
Equa_Fluid< 3, 6, 2, 4 > . . . . .	317
TINS2DT3S . . . . .	617
Equa_Fluid< 4, 12, 3, 9 > . . . . .	317
TINS3DT4S . . . . .	620
Equa_Fluid< 4, 8, 2, 4 > . . . . .	317
NSP2DQ41 . . . . .	522
Equa_Laplace< 2, 2, 1, 1 > . . . . .	319
Laplace1DL2 . . . . .	406
Equa_Laplace< 3, 3, 1, 1 > . . . . .	319
Laplace1DL3 . . . . .	409
Equa_Laplace< 3, 3, 2, 2 > . . . . .	319
Laplace2DT3 . . . . .	413
Equa_Laplace< 4, 4, 3, 3 > . . . . .	319
Equa_Laplace< 6, 6, 3, 3 > . . . . .	319
Laplace2DT6 . . . . .	416
Equa_Porous< 2, 2, 1, 1 > . . . . .	322
Equa_Porous< 3, 3, 2, 2 > . . . . .	322
WaterPorous2D . . . . .	665

Equa.Solid< 2, 12, 1, 6 > . . . . .	325
Beam3DL2 . . . . .	200
Equa.Solid< 2, 4, 1, 2 > . . . . .	325
Bar2DL2 . . . . .	197
Equa.Solid< 3, 6, 2, 4 > . . . . .	325
Elas2DT3 . . . . .	290
Equa.Solid< 4, 12, 3, 9 > . . . . .	325
Elas3DT4 . . . . .	297
Equa.Solid< 4, 8, 2, 4 > . . . . .	325
Elas2DQ4 . . . . .	285
Equa.Solid< 8, 24, 4, 12 > . . . . .	325
Elas3DH8 . . . . .	295
Equa.Therm< 2, 2, 1, 1 > . . . . .	329
DC1DL2 . . . . .	219
Equa.Therm< 3, 3, 2, 2 > . . . . .	329
DC2DT3 . . . . .	224
DC3DAT3 . . . . .	234
Equa.Therm< 4, 4, 3, 3 > . . . . .	329
DC3DT4 . . . . .	238
Equa.Therm< 6, 6, 3, 3 > . . . . .	329
DC2DT6 . . . . .	230
Equa.Electromagnetics< NEN_, NEE_, NSN_, NSE_ > . . . . .	315
Equa.Fluid< NEN_, NEE_, NSN_, NSE_ > . . . . .	317
Equa.Laplace< NEN_, NEE_, NSN_, NSE_ > . . . . .	319
Equa.Porous< NEN_, NEE_, NSN_, NSE_ > . . . . .	322
Equa.Solid< NEN_, NEE_, NSN_, NSE_ > . . . . .	325
Equa.Therm< NEN_, NEE_, NSN_, NSE_ > . . . . .	329
FastMarching . . . . .	349
FastMarching1DG . . . . .	352
FastMarching2DG . . . . .	355
FastMarching3DG . . . . .	359
SteklovPoincare2DBE . . . . .	604
Estimator . . . . .	346
FEShape . . . . .	363
Hexa8 . . . . .	374
Line2 . . . . .	433
Line3 . . . . .	436
Penta6 . . . . .	550
Quad4 . . . . .	569
Tetra4 . . . . .	608
triangle . . . . .	631
Triang3 . . . . .	623
Triang6S . . . . .	626
Figure . . . . .	365
Brick . . . . .	215
Circle . . . . .	217
Ellipse . . . . .	310
Polygon . . . . .	560
Rectangle . . . . .	572
Sphere . . . . .	598
Triangle . . . . .	629
Funct . . . . .	366

Gauss	368
Grid	369
Integration	391
IOField	393
IPF	395
Iter< T_ >	404
Iter< real.t >	404
LinearSolver< T_ >	438
LinearSolver< real.t >	438
LocalMatrix< T_, NR_, NC_ >	446
LocalMatrix< real.t, 2, 2 >	446
LocalVect< T_, N_ >	452
LocalVect< OFELI::Point< real.t >, 3 >	452
LocalVect< real.t, 3 >	452
LocalVect< size.t, 2 >	452
LocalVect< size.t, 3 >	452
LPSolver	457
Material	460
Matrix< T_ >	462
BMatrix< T_ >	211

Prescription . . . . .	567
Reconstruction . . . . .	571
Side . . . . .	574
SideList . . . . .	580
Tabulation . . . . .	606
Timer . . . . .	610
TimeStepping . . . . .	611
Vect< T_ > . . . . .	635
Vect< complex_t > . . . . .	635
Vect< OFELI::Point< real_t > > . . . . .	635
Vect< real_t > . . . . .	635

# Chapter 4

## Class Index

### 4.1 Class List

Here are the classes, structs, unions and interfaces with brief descriptions:

<a href="#">Bar2DL2</a>	To build element equations for Planar Elastic Bar element with 2 DOF (Degrees of Freedom) per node . . . . .	197
<a href="#">Beam3DL2</a>	To build element equations for 3-D beam equations using 2-node lines . . . . .	200
<a href="#">BiotSavart</a>	Class to compute the magnetic induction from the current density using the Biot-Savart formula . . . . .	205
<a href="#">BMatrix&lt; T_ &gt;</a>	To handle band matrices . . . . .	211
<a href="#">Brick</a>	To store and treat a brick (parallelepiped) figure . . . . .	215
<a href="#">Circle</a>	To store and treat a circular figure . . . . .	217
<a href="#">DC1DL2</a>	Builds finite element arrays for thermal diffusion and convection in 1-D using 2-Node elements . . . . .	219
<a href="#">DC2DT3</a>	Builds finite element arrays for thermal diffusion and convection in 2-D domains using 3-Node triangles . . . . .	224
<a href="#">DC2DT6</a>	Builds finite element arrays for thermal diffusion and convection in 2-D domains using 6-Node triangles . . . . .	230
<a href="#">DC3DAT3</a>	Builds finite element arrays for thermal diffusion and convection in 3-D domains with axisymmetry using 3-Node triangles . . . . .	234
<a href="#">DC3DT4</a>	Builds finite element arrays for thermal diffusion and convection in 3-D domains using 4-Node tetrahedra . . . . .	238
<a href="#">DG</a>	Enables preliminary operations and utilities for the Discontinuous Galerkin method . . . . .	242
<a href="#">DMatrix&lt; T_ &gt;</a>	To handle dense matrices . . . . .	244

<a href="#">Domain</a>	To store and treat finite element geometric information . . . . .	256
<a href="#">DSMatrix&lt; T_ &gt;</a>	To handle symmetric dense matrices . . . . .	261
<a href="#">EC2D1T3</a>	Eddy current problems in 2-D domains using solenoidal approximation . . . .	270
<a href="#">EC2D2T3</a>	Eddy current problems in 2-D domains using transversal approximation . . .	273
<a href="#">Edge</a>	To describe an edge . . . . .	276
<a href="#">EdgeList</a>	Class to construct a list of edges having some common properties . . . . .	279
<a href="#">EigenProblemSolver</a>	Class to find eigenvalues and corresponding eigenvectors of a given matrix in a generalized eigenproblem, <i>i.e.</i> Find scalars $\lambda$ and non-null vectors $v$ such that $[K]\{v\} = \lambda[M]\{v\}$ where $[K]$ and $[M]$ are symmetric matrices. The eigenproblem can be originated from a PDE. For this, we will refer to the matrices $K$ and $M$ as <i>Stiffness</i> and <i>Mass</i> matrices respectively . . . . .	280
<a href="#">Elas2DQ4</a>	To build element equations for 2-D linearized elasticity using 4-node quadrilaterals . . . . .	285
<a href="#">Elas2DT3</a>	To build element equations for 2-D linearized elasticity using 3-node triangles	290
<a href="#">Elas3DH8</a>	To build element equations for 3-D linearized elasticity using 8-node hexahedra	295
<a href="#">Elas3DT4</a>	To build element equations for 3-D linearized elasticity using 4-node tetrahedra	297
<a href="#">Element</a>	To store and treat finite element geometric information . . . . .	301
<a href="#">ElementList</a>	Class to construct a list of elements having some common properties . . . . .	309
<a href="#">Ellipse</a>	To store and treat an ellipsoidal figure . . . . .	310
<a href="#">Equa</a>	Mother abstract class to describe equation . . . . .	312
<a href="#">Equa_Electromagnetics&lt; NEN_, NEE_, NSN_, NSE_ &gt;</a>	Abstract class for Electromagnetics <a href="#">Equation</a> classes . . . . .	315
<a href="#">Equa_Fluid&lt; NEN_, NEE_, NSN_, NSE_ &gt;</a>	Abstract class for Fluid Dynamics <a href="#">Equation</a> classes . . . . .	317
<a href="#">Equa_Laplace&lt; NEN_, NEE_, NSN_, NSE_ &gt;</a>	Abstract class for classes about the Laplace equation . . . . .	319
<a href="#">Equa_Porous&lt; NEN_, NEE_, NSN_, NSE_ &gt;</a>	Abstract class for Porous Media Finite Element classes . . . . .	322
<a href="#">Equa_Solid&lt; NEN_, NEE_, NSN_, NSE_ &gt;</a>	Abstract class for Solid Mechanics Finite Element classes . . . . .	325
<a href="#">Equa_Therm&lt; NEN_, NEE_, NSN_, NSE_ &gt;</a>	Abstract class for Heat transfer Finite Element classes . . . . .	329
<a href="#">Equation&lt; NEN_, NEE_, NSN_, NSE_ &gt;</a>	Abstract class for all equation classes . . . . .	333
<a href="#">Estimator</a>	To calculate an a posteriori estimator of the solution . . . . .	346
<a href="#">FastMarching</a>	Class for the fast marching algorithm on uniform grids . . . . .	349

<a href="#">FastMarching1DG</a>	Class for the fast marching algorithm on 1-D uniform grids . . . . .	352
<a href="#">FastMarching2DG</a>	Class for the fast marching algorithm on 2-D uniform grids . . . . .	355
<a href="#">FastMarching3DG</a>	Class for the fast marching algorithm on 3-D uniform grids . . . . .	359
<a href="#">FEShape</a>	Parent class from which inherit all finite element shape classes . . . . .	363
<a href="#">Figure</a>	To store and treat a figure (or shape) information . . . . .	365
<a href="#">Funct</a>	A simple class to parse real valued functions . . . . .	366
<a href="#">Gauss</a>	Calculate data for Gauss integration . . . . .	368
<a href="#">Grid</a>	To manipulate structured grids . . . . .	369
<a href="#">HelmholtzBT3</a>	Builds finite element arrays for Helmholtz equations in a bounded media using 3-Node triangles . . . . .	372
<a href="#">Hexa8</a>	Defines a three-dimensional 8-node hexahedral finite element using Q1-isoparametric interpolation . . . . .	374
<a href="#">ICPG1D</a>	Class to solve the Inviscid compressible fluid flows (Euler equations) for perfect gas in 1-D . . . . .	377
<a href="#">ICPG2DT</a>	Class to solve the Inviscid compressible fluid flows (Euler equations) for perfect gas in 2-D . . . . .	382
<a href="#">ICPG3DT</a>	Class to solve the Inviscid compressible fluid flows (Euler equations) for perfect gas in 3-D . . . . .	387
<a href="#">Integration</a>	Class for numerical integration methods . . . . .	391
<a href="#">IOField</a>	Enables working with files in the XML Format . . . . .	393
<a href="#">IPF</a>	To read project parameters from a file in <a href="#">IPF</a> format . . . . .	395
<a href="#">Iter&lt; T_&gt;</a>	Class to drive an iterative process . . . . .	404
<a href="#">Laplace1DL2</a>	To build element equation for a 1-D elliptic equation using the 2-Node line element (P <sub>1</sub> ) . . . . .	406
<a href="#">Laplace1DL3</a>	To build element equation for the 1-D elliptic equation using the 3-Node line (P <sub>2</sub> ) . . . . .	409
<a href="#">Laplace2DT3</a>	To build element equation for the Laplace equation using the 2-D triangle element (P <sub>1</sub> ) . . . . .	413
<a href="#">Laplace2DT6</a>	To build element equation for the Laplace equation using the 2-D triangle element (P <sub>2</sub> ) . . . . .	416
<a href="#">LaplaceDG2DP1</a>	To build and solve the linear system for the Poisson problem using the <a href="#">DG</a> P <sub>1</sub> 2-D triangle element . . . . .	420

<a href="#">LCL1D</a>	Class to solve the linear conservation law (Hyperbolic equation) in 1-D by a MUSCL Finite Volume scheme . . . . .	423
<a href="#">LCL2DT</a>	Class to solve the linear hyperbolic equation in 2-D by a MUSCL Finite Volume scheme on triangles . . . . .	427
<a href="#">LCL3DT</a>	Class to solve the linear conservation law equation in 3-D by a MUSCL Finite Volume scheme on tetrahedra . . . . .	430
<a href="#">Line2</a>	To describe a 2-Node planar line finite element . . . . .	433
<a href="#">Line3</a>	To describe a 3-Node quadratic planar line finite element . . . . .	436
<a href="#">LinearSolver&lt; T_ &gt;</a>	Class to solve systems of linear equations by iterative methods . . . . .	438
<a href="#">LocalMatrix&lt; T_, NR_, NC_ &gt;</a>	Handles small size matrices like element matrices, with a priori known size . .	446
<a href="#">LocalVect&lt; T_, N_ &gt;</a>	Handles small size vectors like element vectors . . . . .	452
<a href="#">LPSolver</a>	To solve a linear programming problem . . . . .	457
<a href="#">Material</a>	To treat material data. This class enables reading material data in material data files. It also returns these informations by means of its members . . . . .	460
<a href="#">Matrix&lt; T_ &gt;</a>	Virtual class to handle matrices for all storage formats . . . . .	462
<a href="#">Mesh</a>	To store and manipulate finite element meshes . . . . .	471
<a href="#">MeshAdapt</a>	To adapt mesh in function of given solution . . . . .	493
<a href="#">Muscl</a>	Parent class for hyperbolic solvers with Muscl scheme . . . . .	498
<a href="#">Muscl1D</a>	Class for 1-D hyperbolic solvers with <a href="#">Muscl</a> scheme . . . . .	502
<a href="#">Muscl2DT</a>	Class for 2-D hyperbolic solvers with <a href="#">Muscl</a> scheme . . . . .	504
<a href="#">Muscl3DT</a>	Class for 3-D hyperbolic solvers with <a href="#">Muscl</a> scheme using tetrahedra . . . . .	506
<a href="#">MyNLAS</a>	Abstract class to define by user specified function . . . . .	508
<a href="#">MyOpt</a>	Abstract class to define by user specified optimization function . . . . .	509
<a href="#">NLASSolver</a>	To solve a system of nonlinear algebraic equations of the form $f(u) = 0$ . . . . .	511
<a href="#">Node</a>	To describe a node . . . . .	516
<a href="#">NodeList</a>	Class to construct a list of nodes having some common properties . . . . .	520
<a href="#">NSP2DQ41</a>	Builds finite element arrays for incompressible Navier-Stokes equations in 2-D domains using $Q_1/P_0$ element and a penalty formulation for the incompressibility condition . . . . .	522
<a href="#">ODESolver</a>	To solve a system of ordinary differential equations . . . . .	525

<a href="#">OFELIException</a>	To handle exceptions in <a href="#">OFELI</a> . . . . .	537
<a href="#">OptSolver</a>	To solve an optimization problem with bound constraints . . . . .	537
<a href="#">Partition</a>	To partition a finite element mesh into balanced submeshes . . . . .	547
<a href="#">Penta6</a>	Defines a 6-node pentahedral finite element using $P_1$ interpolation in local coordinates $(s.x, s.y)$ and $Q_1$ isoparametric interpolation in local coordinates $(s.x, s.z)$ and $(s.y, s.z)$ . . . . .	550
<a href="#">PhaseChange</a>	This class enables defining phase change laws for a given material . . . . .	553
<a href="#">Point&lt; T_ &gt;</a>	Defines a point with arbitrary type coordinates . . . . .	553
<a href="#">Point2D&lt; T_ &gt;</a>	Defines a 2-D point with arbitrary type coordinates . . . . .	557
<a href="#">Polygon</a>	To store and treat a polygonal figure . . . . .	560
<a href="#">Prec&lt; T_ &gt;</a>	To set a preconditioner . . . . .	562
<a href="#">Prescription</a>	To prescribe various types of data by an algebraic expression. Data may consist in boundary conditions, forces, tractions, fluxes, initial condition. All these data types can be defined through an enumerated variable . . . . .	567
<a href="#">Quad4</a>	Defines a 4-node quadrilateral finite element using $Q_1$ isoparametric interpolation . . . . .	569
<a href="#">Reconstruction</a>	To perform various reconstruction operations . . . . .	571
<a href="#">Rectangle</a>	To store and treat a rectangular figure . . . . .	572
<a href="#">Side</a>	To store and treat finite element sides (edges in 2-D or faces in 3-D) . . . . .	574
<a href="#">SideList</a>	Class to construct a list of sides having some common properties . . . . .	580
<a href="#">SkMatrix&lt; T_ &gt;</a>	To handle square matrices in skyline storage format . . . . .	581
<a href="#">SkSMatrix&lt; T_ &gt;</a>	To handle symmetric matrices in skyline storage format . . . . .	589
<a href="#">Sphere</a>	To store and treat a sphere . . . . .	598
<a href="#">SpMatrix&lt; T_ &gt;</a>	To handle matrices in sparse storage format . . . . .	600
<a href="#">SteklovPoincare2DBE</a>	Solver of the Steklov Poincare problem in 2-D geometries using piecewise constant boundary element . . . . .	604
<a href="#">Tabulation</a>	To read and manipulate tabulated functions . . . . .	606
<a href="#">Tetra4</a>	Defines a three-dimensional 4-node tetrahedral finite element using $P_1$ interpolation . . . . .	608
<a href="#">Timer</a>	To handle elapsed time counting . . . . .	610

<a href="#">TimeStepping</a>	To solve time stepping problems, i.e. systems of linear ordinary differential equations of the form $[A2]\{y''\} + [A1]\{y'\} + [A0]\{y\} = \{b\}$ . . . . .	611
<a href="#">TINS2DT3S</a>	Builds finite element arrays for transient incompressible fluid flow using Navier-Stokes equations in 2-D domains. Numerical approximation uses stabilized 3-node triangle finite elements for velocity and pressure. 2nd-order projection scheme is used for time integration . . . . .	617
<a href="#">TINS3DT4S</a>	Builds finite element arrays for transient incompressible fluid flow using Navier-Stokes equations in 3-D domains. Numerical approximation uses stabilized 4-node tetrahedral finite elements for velocity and pressure. 2nd-order projection scheme is used for time integration . . . . .	620
<a href="#">Triang3</a>	Defines a 3-Node ( $P_1$ ) triangle . . . . .	623
<a href="#">Triang6S</a>	Defines a 6-Node straight triangular finite element using $P_2$ interpolation . . .	626
<a href="#">Triangle</a>	To store and treat a triangle . . . . .	629
<a href="#">triangle</a>	Defines a triangle. The reference element is the rectangle triangle with two unit edges . . . . .	631
<a href="#">TrMatrix&lt; T_ &gt;</a>	To handle tridiagonal matrices . . . . .	633
<a href="#">Vect&lt; T_ &gt;</a>	To handle general purpose vectors . . . . .	635
<a href="#">WaterPorous2D</a>	To solve water flow equations in porous media (1-D) . . . . .	665

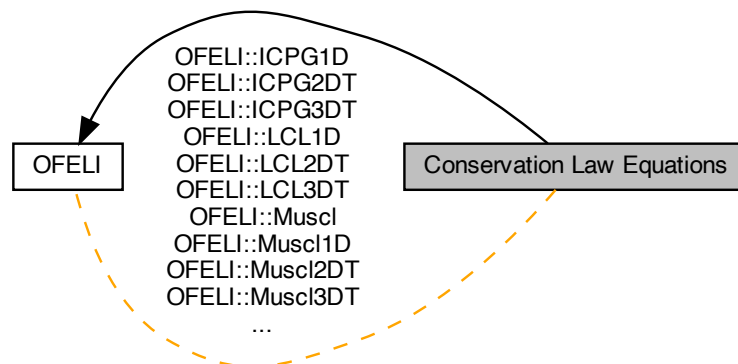

# Chapter 5

## Module Documentation

### 5.1 Conservation Law Equations

Conservation law equations.

Collaboration diagram for Conservation Law Equations:

### Classes

- class [ICPG1D](#)  
*Class to solve the Inviscid compressible fluid flows (Euler equations) for perfect gas in 1-D.*
- class [ICPG2DT](#)  
*Class to solve the Inviscid compressible fluid flows (Euler equations) for perfect gas in 2-D.*
- class [ICPG3DT](#)  
*Class to solve the Inviscid compressible fluid flows (Euler equations) for perfect gas in 3-D.*
- class [LCL1D](#)  
*Class to solve the linear conservation law (Hyperbolic equation) in 1-D by a MUSCL Finite Volume scheme.*
- class [LCL2DT](#)  
*Class to solve the linear hyperbolic equation in 2-D by a MUSCL Finite Volume scheme on triangles.*

- class [LCL3DT](#)  
*Class to solve the linear conservation law equation in 3-D by a MUSCL Finite Volume scheme on tetrahedra.*
- class [Muscl](#)  
*Parent class for hyperbolic solvers with Muscl scheme.*
- class [Muscl1D](#)  
*Class for 1-D hyperbolic solvers with [Muscl](#) scheme.*
- class [Muscl2DT](#)  
*Class for 2-D hyperbolic solvers with [Muscl](#) scheme.*
- class [Muscl3DT](#)  
*Class for 3-D hyperbolic solvers with [Muscl](#) scheme using tetrahedra.*

### 5.1.1 Detailed Description

Conservation law equations.

## 5.2 Electromagnetics

Electromagnetic equations.

Collaboration diagram for Electromagnetics:

### Classes

- class [BiotSavart](#)  
*Class to compute the magnetic induction from the current density using the Biot-Savart formula.*
- class [EC2D1T3](#)  
*Eddy current problems in 2-D domains using solenoidal approximation.*
- class [EC2D2T3](#)  
*Eddy current problems in 2-D domains using transversal approximation.*
- class [Equa\\_Electromagnetics](#)< [NEN\\_](#), [NEE\\_](#), [NSN\\_](#), [NSE\\_](#) >  
*Abstract class for Electromagnetics [Equation](#) classes.*
- class [HelmholtzBT3](#)  
*Builds finite element arrays for Helmholtz equations in a bounded media using 3-Node triangles.*

### 5.2.1 Detailed Description

Electromagnetic equations.

## 5.3 General Purpose Equations

Gathers equation related classes.

Collaboration diagram for General Purpose Equations:

### Classes

- class [Equa](#)  
*Mother abstract class to describe equation.*
- class [Equation](#)< [NEN\\_](#), [NEE\\_](#), [NSN\\_](#), [NSE\\_](#) >  
*Abstract class for all equation classes.*
- class [Estimator](#)  
*To calculate an a posteriori estimator of the solution.*

### Functions

- `template<class T_, size_t N_, class E_>`  
`void element\_assembly (const E_ &e, const LocalVect< T_, N_ > &be, Vect< T_ > &b)`  
*Assemble local vector into global vector.*
- `template<class T_, size_t N_, class E_>`  
`void element\_assembly (const E_ &e, const LocalMatrix< T_, N_, N_ > &ae, Vect< T_ > &b)`  
*Assemble diagonal local vector into global vector.*
- `template<class T_, size_t N_, class E_>`  
`void element\_assembly (const E_ &e, const LocalMatrix< T_, N_, N_ > &ae, Matrix< T_ > *A)`  
*Assemble local matrix into global matrix.*
- `template<class T_, size_t N_, class E_>`  
`void element\_assembly (const E_ &e, const LocalMatrix< T_, N_, N_ > &ae, SkMatrix< T_ > &A)`  
*Assemble local matrix into global skyline matrix.*
- `template<class T_, size_t N_, class E_>`  
`void element\_assembly (const E_ &e, const LocalMatrix< T_, N_, N_ > &ae, SkSMatrix< T_ > &A)`  
*Assemble local matrix into global symmetric skyline matrix.*
- `template<class T_, size_t N_, class E_>`  
`void element\_assembly (const E_ &e, const LocalMatrix< T_, N_, N_ > &ae, SpMatrix< T_ > &A)`  
*Assemble local matrix into global sparse matrix.*

- `template<class T_, size_t N_>`  
`void side\_assembly (const Element &e, const LocalMatrix< T_, N_, N_ > &ae, SpMatrix< T_ > &A)`  
*Side assembly of local matrix into global matrix (as instance of class [SpMatrix](#)).*
- `template<class T_, size_t N_>`  
`void side\_assembly (const Element &e, const LocalMatrix< T_, N_, N_ > &ae, SkSMatrix< T_ > &A)`  
*Side assembly of local matrix into global matrix (as instance of class [SkSMatrix](#)).*
- `template<class T_, size_t N_>`  
`void side\_assembly (const Element &e, const LocalMatrix< T_, N_, N_ > &ae, SkMatrix< T_ > &A)`  
*Side assembly of local matrix into global matrix (as instance of class [SkMatrix](#)).*
- `template<class T_, size_t N_>`  
`void side\_assembly (const Element &e, const LocalVect< T_, N_ > &be, Vect< T_ > &b)`  
*Side assembly of local vector into global vector.*
- `ostream & operator<< (ostream &s, const Estimator &r)`  
*Output estimator vector in output stream.*

### 5.3.1 Detailed Description

Gathers equation related classes.

### 5.3.2 Function Documentation

**`void element_assembly ( const E_ &e, const LocalVect< T_, N_ > &be, Vect< T_ > &b )`**

Assemble local vector into global vector.

Parameters

in	<i>e</i>	Reference to local entity ( <a href="#">Element</a> or <a href="#">Side</a> )
in	<i>be</i>	Local vector
in,out	<i>b</i>	Global vector

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**`void element_assembly ( const E_ &e, const LocalMatrix< T_, N_, N_ > &ae, Vect< T_ > &b )`**

Assemble diagonal local vector into global vector.

Parameters

in	<i>e</i>	Reference to local entity ( <a href="#">Element</a> or <a href="#">Side</a> )
----	----------	---

in	<i>ae</i>	Local matrix
in,out	<i>b</i>	Global vector

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**void element\_assembly ( const E\_ & *e*, const LocalMatrix< T\_, N\_, N\_ > & *ae*, Matrix< T\_ > \* *A* )**

Assemble local matrix into global matrix.

This function is to be called with an abstract pointer to matrix (class [Matrix](#))

Parameters

in	<i>e</i>	Reference to local entity ( <a href="#">Element</a> or <a href="#">Side</a> )
in	<i>ae</i>	Local matrix
in,out	<i>A</i>	Pointer to global matrix

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**void element\_assembly ( const E\_ & *e*, const LocalMatrix< T\_, N\_, N\_ > & *ae*, SkMatrix< T\_ > & *A* )**

Assemble local matrix into global skyline matrix.

Parameters

in	<i>e</i>	Reference to local entity ( <a href="#">Element</a> or <a href="#">Side</a> )
in	<i>ae</i>	Local matrix
in,out	<i>A</i>	Global matrix

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**void element\_assembly ( const E\_ & *e*, const LocalMatrix< T\_, N\_, N\_ > & *ae*, SkSMMatrix< T\_ > & *A* )**

Assemble local matrix into global symmetric skyline matrix.

Parameters

in	$e$	Reference to local entity ( <a href="#">Element</a> or <a href="#">Side</a> )
in	$ae$	Local matrix
in,out	$A$	Global matrix

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**void element\_assembly ( const E\_ &  $e$ , const LocalMatrix< T\_, N\_, N\_ > &  $ae$ , SpMatrix< T\_ > &  $A$  )**

Assemble local matrix into global sparse matrix.

Parameters

in	$e$	Reference to local entity ( <a href="#">Element</a> or <a href="#">Side</a> )
in	$ae$	Local matrix
in,out	$A$	Global matrix

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**void side\_assembly ( const Element &  $e$ , const LocalMatrix< T\_, N\_, N\_ > &  $ae$ , SpMatrix< T\_ > &  $A$  )**

Side assembly of local matrix into global matrix (as instance of class [SpMatrix](#)).

Parameters

in	$e$	Reference to local <a href="#">Element</a>
in	$ae$	Local matrix
in,out	$A$	Global matrix

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**void side\_assembly ( const Element &  $e$ , const LocalMatrix< T\_, N\_, N\_ > &  $ae$ , SkSMatrix< T\_ > &  $A$  )**

Side assembly of local matrix into global matrix (as instance of class [SkSMatrix](#)).

Parameters

in	$e$	Reference to local <a href="#">Element</a>
in	$ae$	Local matrix
in,out	$A$	Global matrix

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**void side\_assembly ( const [Element](#) &  $e$ , const [LocalMatrix](#)<  $T_$ ,  $N_$ ,  $N_$  > &  $ae$ , [SkMatrix](#)<  $T_$  > &  $A$  )**

[Side](#) assembly of local matrix into global matrix (as instance of class [SkMatrix](#)).

Parameters

in	$e$	Reference to local <a href="#">Element</a>
in	$ae$	Local matrix
in,out	$A$	Global matrix

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**void side\_assembly ( const [Element](#) &  $e$ , const [LocalVect](#)<  $T_$ ,  $N_$  > &  $be$ , [Vect](#)<  $T_$  > &  $b$  )**

Side assembly of local vector into global vector.

Parameters

in	$e$	Reference to local <a href="#">Element</a>
in	$be$	Local vector
in,out	$b$	Global vector

Author

Rachid Touzani

GNU Lesser Public License

## 5.4 Fluid Dynamics

Fluid Dynamics equations.

Collaboration diagram for Fluid Dynamics:

### Classes

- class [Equa\\_Fluid](#) < NEN\_, NEE\_, NSN\_, NSE\_ >  
Abstract class for Fluid Dynamics [Equation](#) classes.
- class [NSP2DQ41](#)  
Builds finite element arrays for incompressible Navier-Stokes equations in 2-D domains using  $Q_1/P_0$  element and a penalty formulation for the incompressibility condition.
- class [TINS2DT3S](#)  
Builds finite element arrays for transient incompressible fluid flow using Navier-Stokes equations in 2-D domains. Numerical approximation uses stabilized 3-node triangle finite elements for velocity and pressure. 2nd-order projection scheme is used for time integration.
- class [TINS3DT4S](#)  
Builds finite element arrays for transient incompressible fluid flow using Navier-Stokes equations in 3- $\leftrightarrow$  D domains. Numerical approximation uses stabilized 4-node tetrahedral finite elements for velocity and pressure. 2nd-order projection scheme is used for time integration.

### 5.4.1 Detailed Description

Fluid Dynamics equations.

## 5.5 Laplace equation

Laplace and Poisson equations.

Collaboration diagram for Laplace equation:

### Classes

- class [Equa\\_Laplace](#)< [NEN\\_](#), [NEE\\_](#), [NSN\\_](#), [NSE\\_](#) >  
*Abstract class for classes about the Laplace equation.*
- class [Laplace1DL2](#)  
*To build element equation for a 1-D elliptic equation using the 2-Node line element ( $P_1$ ).*
- class [Laplace1DL3](#)  
*To build element equation for the 1-D elliptic equation using the 3-Node line ( $P_2$ ).*
- class [Laplace2DT3](#)  
*To build element equation for the Laplace equation using the 2-D triangle element ( $P_1$ ).*
- class [Laplace2DT6](#)  
*To build element equation for the Laplace equation using the 2-D triangle element ( $P_2$ ).*
- class [LaplaceDG2DP1](#)  
*To build and solve the linear system for the Poisson problem using the [DG](#)  $P_1$  2-D triangle element.*
- class [SteklovPoincare2DBE](#)  
*Solver of the Steklov Poincare problem in 2-D geometries using piecewise constant boundary elemen.*

### 5.5.1 Detailed Description

Laplace and Poisson equations.

## 5.6 Porous Media problems

Porous Media equation classes.

Collaboration diagram for Porous Media problems:

### Classes

- class [Equa\\_Porous](#)< NEN\_, NEE\_, NSN\_, NSE\_ >

*Abstract class for Porous Media Finite Element classes.*

### 5.6.1 Detailed Description

Porous Media equation classes.

## 5.7 Solid Mechanics

Solid Mechanics finite element equations.

Collaboration diagram for Solid Mechanics:

### Classes

- class [Bar2DL2](#)  
To build element equations for Planar Elastic Bar element with 2 DOF (Degrees of Freedom) per node.
- class [Beam3DL2](#)  
To build element equations for 3-D beam equations using 2-node lines.
- class [Elas2DQ4](#)  
To build element equations for 2-D linearized elasticity using 4-node quadrilaterals.
- class [Elas2DT3](#)  
To build element equations for 2-D linearized elasticity using 3-node triangles.
- class [Elas3DH8](#)  
To build element equations for 3-D linearized elasticity using 8-node hexahedra.
- class [Elas3DT4](#)  
To build element equations for 3-D linearized elasticity using 4-node tetrahedra.
- class [Equa\\_Solid](#)< [NEN\\_](#), [NEE\\_](#), [NSN\\_](#), [NSE\\_](#) >  
Abstract class for Solid Mechanics Finite Element classes.

### 5.7.1 Detailed Description

Solid Mechanics finite element equations.

## 5.8 Heat Transfer

Heat Transfer equations.

Collaboration diagram for Heat Transfer:

### Classes

- class [DC1DL2](#)  
*Builds finite element arrays for thermal diffusion and convection in 1-D using 2-Node elements.*
- class [DC2DT3](#)  
*Builds finite element arrays for thermal diffusion and convection in 2-D domains using 3-Node triangles.*
- class [DC2DT6](#)  
*Builds finite element arrays for thermal diffusion and convection in 2-D domains using 6-Node triangles.*
- class [DC3DAT3](#)  
*Builds finite element arrays for thermal diffusion and convection in 3-D domains with axisymmetry using 3-Node triangles.*
- class [DC3DT4](#)  
*Builds finite element arrays for thermal diffusion and convection in 3-D domains using 4-Node tetrahedra.*
- class [Equa\\_Therm](#)< [NEN\\_](#), [NEE\\_](#), [NSN\\_](#), [NSE\\_](#) >  
*Abstract class for Heat transfer Finite Element classes.*
- class [PhaseChange](#)  
*This class enables defining phase change laws for a given material.*

### 5.8.1 Detailed Description

Heat Transfer equations.

## 5.9 Input/Output

Input/Output utility classes.

Collaboration diagram for Input/Output:

### Classes

- class [IOField](#)  
*Enables working with files in the XML Format.*
- class [IPF](#)  
*To read project parameters from a file in [IPF](#) format.*
- class [Prescription](#)  
*To prescribe various types of data by an algebraic expression. Data may consist in boundary conditions, forces, tractions, fluxes, initial condition. All these data types can be defined through an enumerated variable.*

### Macros

- `#define MAX\_NB\_PAR 50`  
*Maximum number of parameters.*
- `#define MAX\_ARRAY\_SIZE 100`  
*Maximum array size.*
- `#define MAX\_INPUT\_STRING\_LENGTH 100`  
*Maximum string length.*
- `#define FILENAME\_LENGTH 150`  
*Length of a string defining a file name.*
- `#define MAX\_FFT\_SIZE 15`  
*Maximal size for the FFT Table This table can be used by the FFT for any number of points from 2 up to [MAX\\_FFT\\_SIZE](#). For example, if [MAX\\_FFT\\_SIZE](#) = 14, then we can transform anywhere from 2 to  $2^{15}$  = 32,768 points, using the same sine and cosine table.*

#### 5.9.1 Detailed Description

Input/Output utility classes.

#### 5.9.2 Macro Definition Documentation

`#define MAX\_NB\_PAR 50`

Maximum number of parameters.

Used in class IPF

**#define MAX\_ARRAY\_SIZE 100**

Maximum array size.  
Used in class IPF

**#define MAX\_INPUT\_STRING\_LENGTH 100**

Maximum string length.  
Used in class IPF

## 5.10 Utilities

Utility functions and classes.

Collaboration diagram for Utilities:

### Files

- file [OFELI.h](#)  
*Header file that includes all kernel classes of the library.*
- file [OFELI.Config.h](#)  
*File that contains some macros.*
- file [constants.h](#)  
*File that contains some widely used constants.*

### Classes

- class [Func](#)  
*A simple class to parse real valued functions.*
- class [Tabulation](#)  
*To read and manipulate tabulated functions.*
- class [Point< T\\_ >](#)  
*Defines a point with arbitrary type coordinates.*
- class [Point2D< T\\_ >](#)  
*Defines a 2-D point with arbitrary type coordinates.*
- class [OFELIException](#)  
*To handle exceptions in [OFELI](#).*
- class [Gauss](#)  
*Calculate data for Gauss integration.*
- class [Timer](#)  
*To handle elapsed time counting.*

## Macros

- #define OFELI\_E 2.71828182845904523536028747135

## Typedefs

- typedef unsigned long `lsize_t`  
*This type stands for type `unsigned long`.*
- typedef double `real_t`  
*This type stands for `double`.*
- typedef std::complex< double > `complex_t`  
*This type stands for type `std::complex<double>`*

## Functions

- ostream & **operator<<** (ostream &s, const **complex.t** &x)  
*Output a complex number.*
- ostream & **operator<<** (ostream &s, const std::string &c)  
*Output a string.*
- template<class T\_ >  
ostream & **operator<<** (ostream &s, const vector< T\_ > &v)  
*Output a vector instance.*
- template<class T\_ >  
ostream & **operator<<** (ostream &s, const std::list< T\_ > &l)  
*Output a vector instance.*
- template<class T\_ >  
ostream & **operator<<** (ostream &s, const std::pair< T\_, T\_ > &a)  
*Output a pair instance.*
- void **saveField** (Vect< **real.t** > &v, string output\_file, int opt)  
*Save a vector to an output file in a given file format.*
- void **saveField** (const Vect< **real.t** > &v, const Mesh &mesh, string output\_file, int opt)  
*Save a vector to an output file in a given file format.*
- void **saveField** (Vect< **real.t** > &v, const Grid &g, string output\_file, int opt)  
*Save a vector to an output file in a given file format, for a structured grid data.*
- void **saveGnuplot** (string input\_file, string output\_file, string mesh\_file, int f=1)  
*Save a vector to an input **Gnuplot** file.*

- void `saveGnuplot` (Mesh &mesh, string input\_file, string output\_file, int f=1)  
*Save a vector to an input `Gnuplot` file.*
- void `saveTecplot` (string input\_file, string output\_file, string mesh\_file, int f=1)  
*Save a vector to an output file to an input `Tecplot` file.*
- void `saveTecplot` (Mesh &mesh, string input\_file, string output\_file, int f=1)  
*Save a vector to an output file to an input `Tecplot` file.*
- void `saveVTK` (string input\_file, string output\_file, string mesh\_file, int f=1)  
*Save a vector to an output `VTK` file.*
- void `saveVTK` (Mesh &mesh, string input\_file, string output\_file, int f=1)  
*Save a vector to an output `VTK` file.*
- void `saveGmsh` (string input\_file, string output\_file, string mesh\_file, int f=1)  
*Save a vector to an output `Gmsh` file.*
- void `saveGmsh` (Mesh &mesh, string input\_file, string output\_file, int f=1)  
*Save a vector to an output `Gmsh` file.*
- ostream & `operator<<` (ostream &s, const Tabulation &t)  
*Output Tabulated function data.*

*Return discrepancy between 2 vectors x and y*
- `real_t Discrepancy (Vect< complex_t > &x, const Vect< complex_t > &y, int n, int type=1)`  
*Return discrepancy between 2 vectors x and y*
- `void getMesh (string file, ExternalFileFormat form, Mesh &mesh, size_t nb_dof=1)`  
*Construct an instance of class **Mesh** from a mesh file stored in an external file format.*
- `void getBamg (string file, Mesh &mesh, size_t nb_dof=1)`  
*Construct an instance of class **Mesh** from a mesh file stored in **Bamg** format.*
- `void getEasymesh (string file, Mesh &mesh, size_t nb_dof=1)`  
*Construct an instance of class **Mesh** from a mesh file stored in **Easymesh** format.*
- `void getGambit (string file, Mesh &mesh, size_t nb_dof=1)`  
*Construct an instance of class **Mesh** from a mesh file stored in **Gambit** neutral format.*
- `void getGmsh (string file, Mesh &mesh, size_t nb_dof=1)`  
*Construct an instance of class **Mesh** from a mesh file stored in **Gmsh** format.*
- `void getMatlab (string file, Mesh &mesh, size_t nb_dof=1)`  
*Construct an instance of class **Mesh** from a Matlab mesh data.*
- `void getNetgen (string file, Mesh &mesh, size_t nb_dof=1)`  
*Construct an instance of class **Mesh** from a mesh file stored in **Netgen** format.*
- `void getTetgen (string file, Mesh &mesh, size_t nb_dof=1)`  
*Construct an instance of class **Mesh** from a mesh file stored in **Tetgen** format.*
- `void getTriangle (string file, Mesh &mesh, size_t nb_dof=1)`  
*Construct an instance of class **Mesh** from a mesh file stored in **Triangle** format.*
- `void saveMesh (const string &file, const Mesh &mesh, ExternalFileFormat form)`  
*This function saves mesh data a file for a given external format.*
- `void saveGmsh (const string &file, const Mesh &mesh)`  
*This function outputs a **Mesh** instance in a file in **Gmsh** format.*
- `void saveGnuplot (const string &file, const Mesh &mesh)`  
*This function outputs a **Mesh** instance in a file in **Gmsh** format.*
- `void saveMatlab (const string &file, const Mesh &mesh)`  
*This function outputs a **Mesh** instance in a file in **Matlab** format.*
- `void saveTecplot (const string &file, const Mesh &mesh)`  
*This function outputs a **Mesh** instance in a file in **Tecplot** format.*
- `void saveVTK (const string &file, const Mesh &mesh)`

This function outputs a *Mesh* instance in a file in *VTK* format.

- void **saveBamg** (const string &file, Mesh &mesh)

This function outputs a *Mesh* instance in a file in *Bamg* format.

- void **BSpline** (size\_t n, size\_t t, Vect< Point< **real\_t** > > &control, Vect< Point< **real\_t** > > &output, size\_t num\_output)

Function to perform a B-spline interpolation.

- void **banner** (const string &prog=" ")

Outputs a banner as header of any developed program.

- template<class T\_ >  
void **QuickSort** (std::vector< T\_ > &a, int begin, int end)

Function to sort a vector.

- template<class T\_ >  
void **qksort** (std::vector< T\_ > &a, int begin, int end)

Function to sort a vector.

- template<class T\_ , class C\_ >  
void **qksort** (std::vector< T\_ > &a, int begin, int end, C\_ compare)

Function to sort a vector according to a key function.

- int **Sgn** (**real\_t** a)

Return sign of *a*: -1 or 1.

- **real\_t** **Abs2** (**complex\_t** a)

Return square of modulus of complex number *a*

- **real\_t** **Abs2** (**real\_t** a)

Return square of real number *a*

- **real\_t** **Abs** (**real\_t** a)

Return absolute value of *a*

- **real\_t** **Abs** (**complex\_t** a)

Return modulus of complex number *a*

- **real\_t** **Abs** (const Point< **real\_t** > &p)

Return Norm of vector *a*

- **real\_t** **Conjg** (**real\_t** a)

Return complex conjugate of real number *a*

- **complex\_t** **Conjg** (**complex\_t** a)

Return complex conjugate of complex number *a*

- **real\_t** **Max** (**real\_t** a, **real\_t** b, **real\_t** c)

Return maximum value of real numbers *a*, *b* and *c*

- int **Kronecker** (int i, int j)

Return Kronecker delta of *i* and *j*.

- int **Max** (int a, int b, int c)

Return maximum value of integer numbers *a*, *b* and *c*

- **real\_t** **Min** (**real\_t** a, **real\_t** b, **real\_t** c)

Return minimum value of real numbers *a*, *b* and *c*

- int **Min** (int a, int b, int c)

Return minimum value of integer numbers *a*, *b* and *c*

- **real\_t** **Max** (**real\_t** a, **real\_t** b, **real\_t** c, **real\_t** d)

Return maximum value of integer numbers *a*, *b*, *c* and *d*

- int **Max** (int a, int b, int c, int d)

Return maximum value of integer numbers *a*, *b*, *c* and *d*

- **real.t Min** (**real.t** a, **real.t** b, **real.t** c, **real.t** d)  
Return minimum value of real numbers *a*, *b*, *c* and *d*
- **int Min** (int a, int b, int c, int d)  
Return minimum value of integer numbers *a*, *b*, *c* and *d*
- **real.t Arg** (**complex.t** x)  
Return argument of complex number *x*
- **complex.t Log** (**complex.t** x)  
Return principal determination of logarithm of complex number *x*
- **template<class T\_>**  
**T\_ Sqr** (**T\_** x)  
Return square of value *x*
- **template<class T\_>**  
**void Scale** (**T\_** a, const vector< **T\_** > &x, vector< **T\_** > &y)  
Multiply vector *x* by *a* and save result in vector *y*
- **template<class T\_>**  
**void Scale** (**T\_** a, const Vect< **T\_** > &x, Vect< **T\_** > &y)  
Multiply vector *x* by *a* and save result in vector *y*
- **template<class T\_>**  
**void Scale** (**T\_** a, vector< **T\_** > &x)  
Multiply vector *x* by *a*
- **template<class T\_>**  
**void Xpy** (size.t n, **T\_** \*x, **T\_** \*y)  
Add array *x* to *y*
- **template<class T\_>**  
**void Xpy** (const vector< **T\_** > &x, vector< **T\_** > &y)  
Add vector *x* to *y*
- **template<class T\_>**  
**void Axy** (size.t n, **T\_** a, **T\_** \*x, **T\_** \*y)  
Multiply array *x* by *a* and add result to *y*
- **template<class T\_>**  
**void Axy** (**T\_** a, const vector< **T\_** > &x, vector< **T\_** > &y)  
Multiply vector *x* by *a* and add result to *y*
- **template<class T\_>**  
**void Axy** (**T\_** a, const Vect< **T\_** > &x, Vect< **T\_** > &y)  
Multiply vector *x* by *a* and add result to *y*
- **template<class T\_>**  
**void Copy** (size.t n, **T\_** \*x, **T\_** \*y)  
Copy array *x* to *y* *n* is the arrays size.
- **real.t Error2** (const vector< **real.t** > &x, const vector< **real.t** > &y)  
Return absolute L2 error between vectors *x* and *y*
- **real.t RError2** (const vector< **real.t** > &x, const vector< **real.t** > &y)  
Return absolute  $L^2$  error between vectors *x* and *y*
- **real.t ErrorMax** (const vector< **real.t** > &x, const vector< **real.t** > &y)  
Return absolute Max. error between vectors *x* and *y*
- **real.t RErrorMax** (const vector< **real.t** > &x, const vector< **real.t** > &y)  
Return relative Max. error between vectors *x* and *y*
- **template<class T\_>**  
**T\_ Dot** (size.t n, **T\_** \*x, **T\_** \*y)

- Return dot product of arrays  $x$  and  $y$*

  - **real.t Dot** (const vector< **real.t** > & $x$ , const vector< **real.t** > & $y$ )

*Return dot product of vectors  $x$  and  $y$ .*
- template<class T\_ >  
T\_ **Dot** (const Point< T\_ > & $x$ , const Point< T\_ > & $y$ )

*Return dot product of  $x$  and  $y$*
- **real.t exprep** (**real.t**  $x$ )

*Compute the exponential function with avoiding over and underflows.*
- template<class T\_ >  
void **Assign** (vector< T\_ > & $v$ , const T\_ & $a$ )

*Assign the value  $a$  to all entries of a vector  $v$*
- template<class T\_ >  
void **clear** (vector< T\_ > & $v$ )

*Assign 0 to all entries of a vector.*
- template<class T\_ >  
void **clear** (Vect< T\_ > & $v$ )

*Assign 0 to all entries of a vector.*
- **real.t Nrm2** (size\_t  $n$ , **real.t** \* $x$ )

*Return 2-norm of array  $x$*
- **real.t Nrm2** (const vector< **real.t** > & $x$ )

*Return 2-norm of vector  $x$*
- template<class T\_ >  
**real.t Nrm2** (const Point< T\_ > & $a$ )

*Return 2-norm of  $a$*
- bool **Equal** (**real.t**  $x$ , **real.t**  $y$ , **real.t** toler=**OFELLEPSMCH**)

*Function to return true if numbers  $x$  and  $y$  are close up to a given tolerance  $toler$*
- char **itoc** (int  $i$ )

*Function to convert an integer to a character.*
- template<class T\_ >  
T\_ **stringTo** (const std::string & $s$ )

*Function to convert a string to a template type parameter.*

### 5.10.1 Detailed Description

Utility functions and classes.

### 5.10.2 Macro Definition Documentation

**#define OFELI\_E 2.71828182845904523536028747135**

Value of  $e$  or  $exp$  (with 28 digits)

**#define OFELI\_PI 3.14159265358979323846264338328**

Value of  $Pi$  (with 28 digits)

**#define OFELI\_THIRD 0.333333333333333333333333333333**

Value of  $1/3$  (with 28 digits)

**#define OFELI\_SIXTH 0.166666666666666666666666666667**

Value of  $1/6$  (with 28 digits)

**#define OFELI\_TWELVETH 0.083333333333333333333333333333**

Value of  $1/12$  (with 28 digits)

**#define OFELI\_SQRT2 1.41421356237309504880168872421**

Value of  $\sqrt{2}$  (with 28 digits)

**#define OFELI\_SQRT3 1.73205080756887729352744634151**

Value of  $\sqrt{3}$  (with 28 digits)

**#define OFELI\_ONEOVERPI 0.31830988618379067153776752675**

Value of  $1/\pi$  (with 28 digits)

**#define OFELI\_GAUSS2 0.57735026918962576450914878050196**

Value of  $1/\sqrt{3}$  (with 32 digits)

**#define OFELI\_EPSMCH DBL\_EPSILON**

Value of Machine Epsilon

**#define OFELI\_TOLERANCE OFELI\_EPSMCH\*10000**

Default tolerance for an iterative process =  $\text{OFELI\_EPSMCH} * 10000$

**#define VLG 1.e10**

Very large number: A real number for penalty

**#define OFELI\_IMAG std::complex<double>(0.,1.);**

= Unit imaginary number ( $i$ )

**#define CATCH\_EXCEPTION**

**Value:**

```
catch(OFELIException &e) {
    std::cout << "OFELI error: " << e.what() << endl;
    return 1;
}
catch(runtime_error &e) {
    std::cout << "OFELI Runtime error: " << e.what() << endl;
    return 1;
}
catch( ... ) {
    std::cout << "OFELI Unexpected error: " << endl;
    return 1;
}
```

This macro can be inserted after a try loop to catch a thrown exception.

### 5.10.3 Function Documentation

**ostream & operator<< ( ostream & s, const complex\_t & x )**

Output a complex number.

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**ostream & operator<< ( ostream & s, const std::string & c )**

Output a string.

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**ostream & operator<< ( ostream & s, const vector< T\_ > & v )**

Output a vector instance.

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**ostream & operator<< ( ostream & s, const std::list< T\_ > & l )**

Output a vector instance.

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**ostream & operator<< ( ostream & s, const std::pair< T\_, T\_ > & a )**

Output a pair instance.

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**void saveField ( Vect< real.t > & v, string output\_file, int opt )**

Save a vector to an output file in a given file format.

Case where the vector contains mesh information

Parameters

in	<i>v</i>	<a href="#">Vect</a> instance to save
in	<i>output_file</i>	Output file where to save the vector
in	<i>opt</i>	Option to choose file format to save. This is to be chosen among enumerated values: GMSH GNUPLOT MATLAB TECPLOT VTK

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**void saveField ( const Vect< real.t > & v, const Mesh & mesh, string output\_file, int opt )**

Save a vector to an output file in a given file format.

Case where the vector does not contain mesh information

Parameters

in	<i>v</i>	<a href="#">Vect</a> instance to save
in	<i>mesh</i>	<a href="#">Mesh</a> instance
in	<i>output_file</i>	Output file where to save the vector
in	<i>opt</i>	Option to choose file format to save. This is to be chosen among enumerated values: GMSH, GNUPLOT, MATLAB, TECPLOT, VTK

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**void saveField ( Vect< real.t > & v, const Grid & g, string output\_file, int opt = VTK )**

Save a vector to an output file in a given file format, for a structured grid data.

Parameters

in	<i>v</i>	<a href="#">Vect</a> instance to save
in	<i>g</i>	<a href="#">Grid</a> instance
in	<i>output_file</i>	Output file where to save the vector
in	<i>opt</i>	Option to choose file format to save. This is to be chosen among enumerated values: GMSH, VTK

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**void saveGnuplot ( string *input\_file*, string *output\_file*, string *mesh\_file*, int *f* = 1 )**

Save a vector to an input **Gnuplot** file.

Gnuplot is a command-line driven program for producing 2D and 3D plots. It is under the GNU General Public License. Available information can be found in the site:

<http://www.gnuplot.info/>

Parameters

in	<i>input_file</i>	Input file ( <b>OFELI</b> XML file containing a field).
in	<i>output_file</i>	Output file (gnuplot format file)
in	<i>mesh_file</i>	File containing mesh data
in	<i>f</i>	Field is stored each <i>f</i> time step [Default: 1]

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**void saveGnuplot ( Mesh & *mesh*, string *input\_file*, string *output\_file*, int *f* = 1 )**

Save a vector to an input **Gnuplot** file.

Gnuplot is a command-line driven program for producing 2D and 3D plots. It is under the GNU General Public License. Available information can be found in the site:

<http://www.gnuplot.info/>

Parameters

in	<i>mesh</i>	Reference to <b>Mesh</b> instance
in	<i>input_file</i>	Input file ( <b>OFELI</b> XML file containing a field).
in	<i>output_file</i>	Output file (gnuplot format file)
in	<i>f</i>	Field is stored each <i>f</i> time step [Default: 1]

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**void saveTecplot ( string *input\_file*, string *output\_file*, string *mesh\_file*, int *f* = 1 )**

Save a vector to an output file to an input **Tecplot** file.

Tecplot is high quality post graphical commercial processing program developed by **Amtec**. Available information can be found in the site: <http://www.tecplot.com>

Parameters

in	<i>input_file</i>	Input file ( <b>OFELI</b> XML file containing a field).
----	-------------------	---

<code>in</code>	<code>output_file</code>	Output file (gnuplot format file)
<code>in</code>	<code>mesh_file</code>	File containing mesh data
<code>in</code>	<code>f</code>	Field is stored each <code>f</code> time step [Default: 1]

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**void saveTecplot ( Mesh & *mesh*, string *input\_file*, string *output\_file*, int *f* = 1 )**

Save a vector to an output file to an input **Tecplot** file.

Tecplot is high quality post graphical commercial processing program developed by **Amtec**.

Available information can be found in the site: <http://www.tecplot.com>

Parameters

<code>in</code>	<code>mesh</code>	Reference to <b>Mesh</b> instance
<code>in</code>	<code>input_file</code>	Input file ( <b>OFELI</b> XML file containing a field).
<code>in</code>	<code>output_file</code>	Output file (gnuplot format file)
<code>in</code>	<code>f</code>	Field is stored each <code>f</code> time step [Default: 1]

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**saveVTK ( string *input\_file*, string *output\_file*, string *mesh\_file*, int *f* = 1 )**

Save a vector to an output **VTK** file.

The Visualization ToolKit (VTK) is an open source, freely available software system for 3D computer graphics. Available information can be found in the site:

<http://public.kitware.com/VTK/>

Parameters

<code>in</code>	<code>input_file</code>	Input file ( <b>OFELI</b> XML file containing a field).
<code>in</code>	<code>output_file</code>	Output file (VTK format file)
<code>in</code>	<code>mesh_file</code>	File containing mesh data
<code>in</code>	<code>f</code>	Field is stored each <code>f</code> time step [Default: 1]

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**saveVTK ( Mesh & *mesh*, string *input\_file*, string *output\_file*, int *f* = 1 )**

Save a vector to an output **VTK** file.

The Visualization ToolKit (VTK) is an open source, freely available software system for 3D computer graphics. Available information can be found in the site:

<http://public.kitware.com/VTK/>

## Parameters

<code>in</code>	<code>mesh</code>	Reference to <a href="#">Mesh</a> instance
<code>in</code>	<code>input_file</code>	Input file ( <a href="#">OFELI</a> XML file containing a field).
<code>in</code>	<code>output_file</code>	Output file (VTK format file)
<code>in</code>	<code>f</code>	Field is stored each <code>f</code> time step [Default: 1]

**void saveGmsh ( string *input\_file*, string *output\_file*, string *mesh\_file*, int *f* = 1 )**

Save a vector to an output [Gmsh](#) file.

[Gmsh](#) is a free mesh generator and postprocessor that can be downloaded from the site:  
<http://www.geuz.org/gmsh/>

## Parameters

<code>in</code>	<code>input_file</code>	Input file ( <a href="#">OFELI</a> XML file containing a field).
<code>in</code>	<code>output_file</code>	Output file (Gmsh format file)
<code>in</code>	<code>mesh_file</code>	File containing mesh data
<code>in</code>	<code>f</code>	Field is stored each <code>f</code> time step [Default: 1]

**void saveGmsh ( Mesh & *mesh*, string *input\_file*, string *output\_file*, int *f* = 1 )**

Save a vector to an output [Gmsh](#) file.

[Gmsh](#) is a free mesh generator and postprocessor that can be downloaded from the site:  
<http://www.geuz.org/gmsh/>

## Parameters

<code>in</code>	<code>mesh</code>	Reference to <a href="#">Mesh</a> instance
<code>in</code>	<code>input_file</code>	Input file ( <a href="#">OFELI</a> XML file containing a field).
<code>in</code>	<code>output_file</code>	Output file (Gmsh format file)
<code>in</code>	<code>f</code>	Field is stored each <code>f</code> time step [Default: 1]

**real\_t Discrepancy ( Vect< real\_t > & x, const Vect< real\_t > & y, int n, int type = 1 )**

Return discrepancy between 2 vectors x and y

Parameters

in,out	<i>x</i>	First vector (Instance of class <a href="#">Vect</a> ). On output, x is assigned the vector y
in	<i>y</i>	Second vector (Instance of class <a href="#">Vect</a> )
in	<i>n</i>	Type of norm <ul style="list-style-type: none"> <li>• 1: Weighted 1-Norm</li> <li>• 2: Weighted 2-Norm</li> <li>• 0: Max-Norm</li> </ul>
in	<i>type</i>	Discrepancy type (0: Absolute, 1: Relative [Default])

Returns

Computed discrepancy value

**real\_t Discrepancy ( Vect< complex\_t > & x, const Vect< complex\_t > & y, int n, int type = 1 )**

Return discrepancy between 2 vectors x and y

## Parameters

in,out	$x$	First vector (Instance of class <a href="#">Vect</a> ). On output, x is assigned the vector y
in	$y$	Second vector (Instance of class <a href="#">Vect</a> )
in	$n$	Type of norm <ul style="list-style-type: none"> <li>• 1: Weighted 1-Norm</li> <li>• 2: Weighted 2-Norm</li> <li>• 0: Max-Norm</li> </ul>
in	$type$	Discrepancy type (0: Absolute, 1: Relative [Default])

## Returns

Computed discrepancy value

**void getMesh ( string *file*, ExternalFileFormat *form*, Mesh & *mesh*, size\_t *nb\_dof* = 1 )**

Construct an instance of class [Mesh](#) from a mesh file stored in an external file format.

## Parameters

in	<i>file</i>	Input mesh file name.
in	<i>form</i>	Format of the mesh file. This one can be chosen among the enumerated values: <ul style="list-style-type: none"> <li>• GMSH: Mesh generator <b>Gmsh</b>, see site: <a href="http://www.geuz.org/gmsh/">http://www.geuz.org/gmsh/</a></li> <li>• MATLAB: Matlab file, see site: <a href="http://www.mathworks.com/products/matlab/">http://www.mathworks.com/products/matlab/</a></li> <li>• EASYMESH: <b>Easymesh</b> is a 2-D mesh generator, see site: <a href="http://web.mit.edu/easymesh_v1.4/www/easymesh.html">http://web.mit.edu/easymesh_v1.4/www/easymesh.html</a></li> <li>• GAMBIT: <b>Gambit</b> is a mesh generator associated to <b>Fluent</b> <a href="http://www.stanford.edu/class/me469b/gambit_↔download.html">http://www.stanford.edu/class/me469b/gambit_↔download.html</a></li> <li>• BAMG: Mesh generator Bang, see site: <a href="http://raweb.inria.fr/rapportsactivite/R↔A2002/gamma/uid25.html">http://raweb.inria.fr/rapportsactivite/R↔A2002/gamma/uid25.html</a></li> <li>• NETGEN: <b>Netgen</b> is a 3-D mesh generator, see site: <a href="http://www.hpfem.jku.at/netgen/">http://www.hpfem.jku.at/netgen/</a></li> <li>• TETGEN: <b>Tetgen</b> is a 3-D mesh generator, see site: <a href="http://tetgen.berlios.de/">http://tetgen.berlios.de/</a></li> <li>• TRIANGLE_FF: <b>Triangle</b> is a 2-D mesh generator, see site: <a href="http://www.cs.cmu.edu/~quake/triangle.html">http://www.cs.cmu.edu/~quake/triangle.html</a></li> </ul>
out	<i>mesh</i>	<a href="#">Mesh</a> instance created by the function.
in	<i>nb_dof</i>	Number of degrees of freedom for each node. This information is not provided, in general, by mesh generators. Its default value here is 1.

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**void getBamg ( string *file*, Mesh & *mesh*, size\_t *nb\_dof* = 1 )**

Construct an instance of class [Mesh](#) from a mesh file stored in [Bamg](#) format.

Parameters

in	<i>file</i>	Name of a file written in the Bamg format.
----	-------------	--

Note

**Bamg** is a 2-D mesh generator. It allows to construct adapted meshes from a given metric. It was developed at INRIA, France. Available information can be found in the site:

<http://raweb.inria.fr/rapportsactivite/RA2002/gamma/uid25.html>

Parameters

out	<i>mesh</i>	<a href="#">Mesh</a> instance created by the function.
in	<i>nb_dof</i>	Number of degrees of freedom for each node. This information is not provided, in general, by mesh generators. Its default value here is 1.

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**void getEasymesh ( string *file*, Mesh & *mesh*, size\_t *nb\_dof* = 1 )**

Construct an instance of class [Mesh](#) from a mesh file stored in [Easymesh](#) format.

Parameters

in	<i>file</i>	Name of a file (without extension) written in <b>Easymesh</b> format. Actually, the function <code>Easymesh2MDF</code> attempts to read mesh data from files <code>file.e</code> , <code>file.n</code> and <code>file.s</code> produced by <b>Easymesh</b> .
----	-------------	--

Note

**Easymesh** is a free program that generates 2-D, unstructured, Delaunay and constrained Delaunay triangulations in general domains. It can be downloaded from the site:

<http://www-dinma.univ.trieste.it/nirftc/research/easymesh/Default.htm>

## Parameters

in	<i>mesh</i>	<a href="#">Mesh</a> instance created by the function.
in	<i>nb_dof</i>	Number of degrees of freedom for each node. This information is not provided, in general, by mesh generators. Its default value here is 1.

## Author

Rachid Touzani

## Copyright

GNU Lesser Public License

```
void getGambit ( string file, Mesh & mesh, size_t nb_dof = 1 )
```

Construct an instance of class [Mesh](#) from a mesh file stored in **Gambit** neutral format.

## Note

**Gambit** is a commercial mesh generator associated to the CFD code **Fluent**. Informations about **Gambit** can be found in the site:

<http://www.fluent.com/software/gambit/>

## Parameters

in	<i>file</i>	Name of a file written in the <b>Gambit</b> neutral format.
out	<i>mesh</i>	<a href="#">Mesh</a> instance created by the function.
in	<i>nb_dof</i>	Number of degrees of freedom for each node. This information is not provided, in general, by mesh generators. Its default value here is 1.

## Author

Rachid Touzani

## Copyright

GNU Lesser Public License

```
void getGmsh ( string file, Mesh & mesh, size_t nb_dof = 1 )
```

Construct an instance of class [Mesh](#) from a mesh file stored in **Gmsh** format.

## Note

**Gmsh** is a free mesh generator that can be downloaded from the site:

<http://www.geuz.org/gmsh/>

## Parameters

in	<i>file</i>	Name of a file written in the <b>Gmsh</b> format.
out	<i>mesh</i>	<a href="#">Mesh</a> instance created by the function.
in	<i>nb_dof</i>	Number of degrees of freedom for each node. This information is not provided, in general, by mesh generators. Its default value here is 1.

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**void getMatlab ( string *file*, Mesh & *mesh*, size\_t *nb\_dof* = 1 )**

Construct an instance of class [Mesh](#) from a Matlab mesh data.

Note

**Matlab** is a language of scientific computing including visualization. It is developed by [MathWorks](#). Available information can be found in the site:  
<http://www.mathworks.com/products/matlab/>

Parameters

in	<i>file</i>	Name of a file created by Matlab by executing the script file <code>Matlab2OFELI.m</code>
out	<i>mesh</i>	<a href="#">Mesh</a> instance created by the function.
in	<i>nb_dof</i>	Number of degrees of freedom for each node. This information is not provided, in general, by mesh generators. Its default value here is 1.

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**void getNetgen ( string *file*, Mesh & *mesh*, size\_t *nb\_dof* = 1 )**

Construct an instance of class [Mesh](#) from a mesh file stored in **Netgen** format.

Note

**Netgen** is a tetrahedral mesh generator that can be downloaded from the site:  
<http://www.hpfem.jku.at/netgen/>

## Parameters

in	<i>file</i>	Name of a file written in the Netgen format.
out	<i>mesh</i>	<a href="#">Mesh</a> instance created by the function.
in	<i>nb_dof</i>	Number of degrees of freedom for each node. This information is not provided, in general, by mesh generators. [ default = 1 ]

## Author

Rachid Touzani

## Copyright

GNU Lesser Public License

**void getTetgen ( string *file*, Mesh & *mesh*, size\_t *nb\_dof* = 1 )**

Construct an instance of class [Mesh](#) from a mesh file stored in [Tetgen](#) format.

## Note

**Tetgen** is a free three-dimensional mesh generator that can be downloaded in the site:  
<http://tetgen.berlios.de/>

## Parameters

in	<i>file</i>	Name of a file written in the <b>Tetgen</b> format.
out	<i>mesh</i>	<a href="#">Mesh</a> instance created by the function.
in	<i>nb_dof</i>	Number of degrees of freedom for each node. This information is not provided, in general, by mesh generators. Its default value here is 1.

## Author

Rachid Touzani

## Copyright

GNU Lesser Public License

**void getTriangle ( string *file*, Mesh & *mesh*, size\_t *nb\_dof* = 1 )**

Construct an instance of class [Mesh](#) from a mesh file stored in [Triangle](#) format.

## Note

**TRIANGLE** is a C program that can generate meshes, Delaunay triangulations and Voronoi diagrams for 2D pointsets that can be downloaded in the site:  
[http://people.scs.fsu.edu/~burkardt/c\\_src/triangle/triangle.html/](http://people.scs.fsu.edu/~burkardt/c_src/triangle/triangle.html/)

## Parameters

in	<i>file</i>	Name of a file written in the <b>Tetgen</b> format.
out	<i>mesh</i>	<a href="#">Mesh</a> instance created by the function.
in	<i>nb_dof</i>	Number of degrees of freedom for each node. This information is not provided, in general, by mesh generators. Its default value here is 1.

## Author

Rachid Touzani

## Copyright

GNU Lesser Public License

**void saveMesh ( const string &file, const Mesh &mesh, ExternalFileFormat form )**

This function saves mesh data a file for a given external format.

## Parameters

in	<i>file</i>	File where to store mesh
in	<i>mesh</i>	<a href="#">Mesh</a> instance to save
in	<i>form</i>	Format of the mesh file. This one can be chosen among the enumerated values: <ul style="list-style-type: none"> <li>• GMSH: Mesh generator and graphical postprocessor <b>Gmsh</b>: <a href="http://www.geuz.org/gmsh/">http://www.geuz.org/gmsh/</a></li> <li>• GNUPLOT: Well known graphics software: <a href="http://www.gnuplot.info/">http://www.gnuplot.info/</a></li> <li>• MATLAB: Matlab file: <a href="http://www.mathworks.com/products/matlab/">http://www.mathworks.com/products/matlab/</a></li> <li>• TECPLOT: Commercial graphics software: <a href="http://www.tecplot.com">http://www.tecplot.com</a></li> <li>• VTK: Graphics format for the free postprocessor <b>ParaView</b>: <a href="http://public.kitware.com/VTK/">http://public.kitware.com/VTK/</a></li> </ul>

**void saveGmsh ( const string &file, const Mesh &mesh )**

This function outputs a [Mesh](#) instance in a file in **Gmsh** format.

## Note

**Gmsh** is a free mesh generator that can be downloaded from the site: <http://www.geuz.org/gmsh/>

## Parameters

out	<i>file</i>	Output file in <b>Gmsh</b> format.
in	<i>mesh</i>	<a href="#">Mesh</a> instance to save.

## Author

Rachid Touzani

## Copyright

GNU Lesser Public License

**void saveGnuplot ( const string & *file*, const Mesh & *mesh* )**

This function outputs a [Mesh](#) instance in a file in **Gmsh** format.

## Note

**Gnuplot** is a command-line driven program for producing 2D and 3D plots. It is under the GNU General Public License. Available information can be found in the site:

<http://www.gnuplot.info/>

## Parameters

out	<i>file</i>	Output file in <b>Gnuplot</b> format.
in	<i>mesh</i>	<a href="#">Mesh</a> instance to save.

## Author

Rachid Touzani

## Copyright

GNU Lesser Public License

**void saveMatlab ( const string & *file*, const Mesh & *mesh* )**

This function outputs a [Mesh](#) instance in a file in **Matlab** format.

## Note

**Matlab** is a language of scientific computing including visualization. It is developed by **MathWorks**. Available information can be found in the site:

<http://www.mathworks.com/products/matlab/>

## Parameters

out	<i>file</i>	Output file in <b>Matlab</b> format.
in	<i>mesh</i>	<a href="#">Mesh</a> instance to save.

## Author

Rachid Touzani

## Copyright

GNU Lesser Public License

**void saveTecplot ( const string &file, const Mesh &mesh )**

This function outputs a **Mesh** instance in a file in **Tecplot** format.

Note

**Tecplot** is high quality post graphical commercial processing program developed by **Amtec**. Available information can be found in the site:

<http://www.tecplot.com>

Parameters

out	<i>file</i>	Output file in <b>Tecplot</b> format.
in	<i>mesh</i>	<b>Mesh</b> instance to save.

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**void saveVTK ( const string &file, const Mesh &mesh )**

This function outputs a **Mesh** instance in a file in **VTK** format.

Note

The Visualization ToolKit (VTK) is an open source, freely available software system for 3D computer graphics. Available information can be found in the site:

<http://public.kitware.com/VTK/>

Parameters

out	<i>file</i>	Output file in <b>VTK</b> format.
in	<i>mesh</i>	<b>Mesh</b> instance to save.

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**void saveBamg ( const string &file, Mesh &mesh )**

This function outputs a **Mesh** instance in a file in **Bamg** format.

Parameters

in	<i>file</i>	Name of a file written in the Bamg format.
----	-------------	--

Note

**Bamg** is a 2-D mesh generator. It allows to construct adapted meshes from a given metric. It was developed at INRIA, France. Available information can be found in the site:

<http://raweb.inria.fr/rapportsactivite/RA2002/gamma/uid25.html>

Parameters

<b>in</b>	<i>mesh</i>	<a href="#">Mesh</a> instance.
-----------	-------------	--------------------------------

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**BSpline ( size\_t n, size\_t t, Vect< Point< real\_t > > & control, Vect< Point< real\_t > > & output, size\_t num\_output )**

Function to perform a B-spline interpolation.

This program is adapted from a free program distributed by Keith Vertanen ([vertankd@cda.ums.mrs.umn.edu](mailto:vertankd@cda.ums.mrs.umn.edu)) in 1994.

Parameters

<b>in</b>	<i>n</i>	Number of control points minus 1.
<b>in</b>	<i>t</i>	Degree of the polynomial plus 1.
<b>in</b>	<i>control</i>	Control point array made up of <a href="#">Point</a> structure.
<b>out</b>	<i>output</i>	Vector in which the calculated spline points are to be put.
<b>in</b>	<i>num_output</i>	How many points on the spline are to be calculated.

Note

Condition:  $n+2 > t$  (No curve results if  $n+2 \leq t$ ) Control vector contains the number of points specified by *n* Output array is the proper size to hold *num\_output* point structures

**void banner ( const string & prog = " " )**

Outputs a banner as header of any developed program.

Parameters

<b>in</b>	<i>prog</i>	Calling program name. Enables writing a copyright notice accompanying the program.
-----------	-------------	--

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**void QuickSort ( std::vector< T\_ > & a, int begin, int end )**

Function to sort a vector.

qksort uses the famous quick sorting algorithm.

Parameters

<b>in,out</b>	<i>a</i>	Vector to sort.
<b>in</b>	<i>begin</i>	index of starting iterator
<b>in</b>	<i>end</i>	index of ending iterator

The calling program must provide an overloading of the operator < for the type **T**.

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**void qksort ( std::vector< T\_ > & a, int begin, int end )**

Function to sort a vector.

qksort uses the famous quick sorting algorithm.

Parameters

<b>in,out</b>	<i>a</i>	Vector to sort.
<b>in</b>	<i>begin</i>	index of starting index (default value is 0)
<b>in</b>	<i>end</i>	index of ending index (default value is the vector size - 1)

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**void qksort ( std::vector< T\_ > & a, int begin, int end, C\_ compare )**

Function to sort a vector according to a key function.

qksort uses the famous quick sorting algorithm.

Parameters

<b>in,out</b>	<i>a</i>	Vector to sort.
<b>in</b>	<i>begin</i>	index of starting index (0 for the beginning of the vector)
<b>in</b>	<i>end</i>	index of ending index
<b>in</b>	<i>compare</i>	A function object that implements the ordering. The user must provide this function that returns a boolean function that is true if the first argument is less than the second and false if not.

**void Scale ( T\_ a, const vector< T\_ > & x, vector< T\_ > & y )**

Multiply vector x by a and save result in vector y  
x and y are instances of class vector<T\_>

**void Scale ( T\_ a, const Vect< T\_ > & x, Vect< T\_ > & y )**

Multiply vector x by a and save result in vector y  
x and y are instances of class Vect<T\_>

**void Scale ( T\_ a, vector< T\_ > & x )**

Multiply vector x by a  
x is an instance of class vector<T\_>

**void Xpy ( const vector< T\_ > & x, vector< T\_ > & y )**

Add vector x to y  
x and y are instances of class vector<T\_>

**void Apxy ( size\_t n, T\_ a, T\_ \* x, T\_ \* y )**

Multiply array x by a and add result to y  
n is the arrays size.

**void Apxy ( T\_ a, const vector< T\_ > & x, vector< T\_ > & y )**

Multiply vector x by a and add result to y  
x and y are instances of class vector<T\_>

**void Apxy ( T\_ a, const Vect< T\_ > & x, Vect< T\_ > & y )**

Multiply vector x by a and add result to y  
x and y are instances of class Vect<T\_>

**T\_ Dot ( size\_t n, T\_ \* x, T\_ \* y )**

Return dot product of arrays x and y  
n is the arrays size.

**double Dot ( const vector< real\_t > & x, const vector< real\_t > & y )**

Return dot product of vectors x and y.  
x and y are instances of class vector<double>

**void clear ( vector< T\_ > & v )**

Assign 0 to all entries of a vector.  
Parameters

in	v	Vector to clear
----	---	-----------------

**void clear ( Vect< T\_ > & v )**

Assign 0 to all entries of a vector.

Parameters

<code>in</code>	<code>v</code>	Vector to clear
-----------------	----------------	-----------------

**`real_t Nrm2 ( size_t n, real_t * x )`**

Return 2-norm of array `x`

Parameters

<code>in</code>	<code>n</code>	is Array length
<code>in</code>	<code>x</code>	Array to treat

**`bool Equal ( real_t x, real_t y, real_t toler = OFELI_EPSMCH )`**

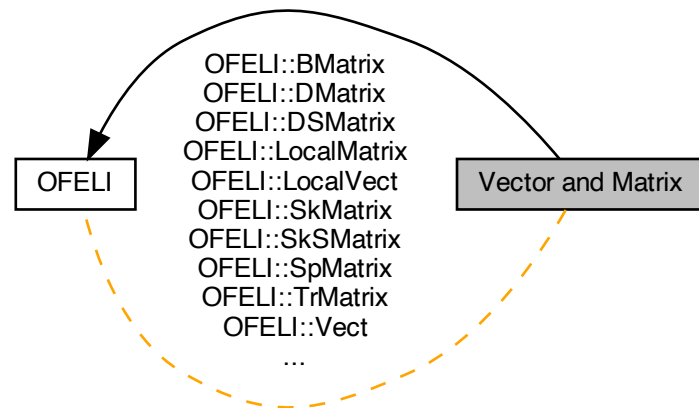

Function to return true if numbers `x` and `y` are close up to a given tolerance `toler`

Default value of tolerance is the constant `OFELI_EPSMCH`

## 5.11 Vector and Matrix

Vector and matrix classes.

Collaboration diagram for Vector and Matrix:

### Classes

- class [BMatrix< T\\_ >](#)  
*To handle band matrices.*
- class [DMatrix< T\\_ >](#)  
*To handle dense matrices.*
- class [DSMatrix< T\\_ >](#)  
*To handle symmetric dense matrices.*
- class [LocalMatrix< T\\_, NR\\_, NC\\_ >](#)  
*Handles small size matrices like element matrices, with a priori known size.*
- class [LocalVect< T\\_, N\\_ >](#)  
*Handles small size vectors like element vectors.*
- class [SkMatrix< T\\_ >](#)  
*To handle square matrices in skyline storage format.*
- class [SkSMatrix< T\\_ >](#)  
*To handle symmetric matrices in skyline storage format.*
- class [SpMatrix< T\\_ >](#)  
*To handle matrices in sparse storage format.*
- class [TrMatrix< T\\_ >](#)  
*To handle tridiagonal matrices.*
- class [Vect< T\\_ >](#)  
*To handle general purpose vectors.*

## Functions

- `template<class T_>`

`ostream & operator<< (ostream &s, const SpMatrix< TT_> &A)`

### 5.11.1 Detailed Description

Vector and matrix classes.

### 5.11.2 Function Documentation

`Vect< T_> operator* ( const BMatrix< T_> & A, const Vect< T_> & b )`

Operator \* (Multiply vector by matrix and return resulting vector.

Parameters

in	$A$	<a href="#">BMatrix</a> instance to multiply by vector
in	$b$	<a href="#">Vect</a> instance

Returns

[Vect](#) instance containing  $A*b$

**BMatrix< T\_ > operator\* ( T\_ a, const BMatrix< T\_ > & A )**

Operator \* (Premultiplication of matrix by constant)

Returns

$a*A$

**Vect< T\_ > operator\* ( const DMatrix< T\_ > & A, const Vect< T\_ > & b )**

Operator \* (Multiply vector by matrix and return resulting vector.

Parameters

in	$A$	<a href="#">DMatrix</a> instance to multiply by vector
in	$b$	<a href="#">Vect</a> instance

Returns

[Vect](#) instance containing  $A*b$

**Vect< T\_ > operator\* ( const DSMatrix< T\_ > & A, const Vect< T\_ > & b )**

Operator \* (Multiply vector by matrix and return resulting vector.

Parameters

in	$A$	<a href="#">DSMatrix</a> instance to multiply by vector
in	$b$	<a href="#">Vect</a> instance

Returns

[Vect](#) instance containing  $A*b$

**LocalMatrix< T\_, NR\_, NC\_ > operator\* ( T\_ a, const LocalMatrix< T\_, NR\_, NC\_ > & x )**

Operator \* (Multiply matrix x by scalar a)

Returns

$a*x$

**LocalVect< T\_, NR\_, NC\_ > operator\* ( const LocalMatrix< T\_, NR\_, NC\_ > & x, const LocalVect< T\_, NC\_ > & x )**

Operator \* (Multiply matrix A by vector x)

This function performs a matrix-vector product and returns resulting vector as a reference to [LocalVect](#) instance

Returns

A\*x

**LocalMatrix< T\_, NR\_, NC\_ > operator/ ( T\_ a, const LocalMatrix< T\_, NR\_, NC\_ > & x )**

Operator / (Divide matrix x by scalar a)

Returns

x/a

**LocalMatrix< T\_, NR\_, NC\_ > operator+ ( const LocalMatrix< T\_, NR\_, NC\_ > & x, const LocalMatrix< T\_, NR\_, NC\_ > & y )**

Operator + (Add matrix x to y)

Returns

x+y

**LocalMatrix< T\_, NR\_, NC\_ > operator- ( const LocalMatrix< T\_, NR\_, NC\_ > & x, const LocalMatrix< T\_, NR\_, NC\_ > & y )**

Operator - (Subtract matrix y from x)

Returns

x-y

**LocalVect< T\_, N\_ > operator+ ( const LocalVect< T\_, N\_ > & x, const LocalVect< T\_, N\_ > & y )**

Operator + (Add two vectors)

Returns

x+y

**LocalVect< T\_, N\_ > operator- ( const LocalVect< T\_, N\_ > & x, const LocalVect< T\_, N\_ > & y )**

Operator - (Subtract two vectors)

Returns

x-y

**LocalVect< T\_, N\_ > operator\* ( T\_ a, const LocalVect< T\_, N\_ > & x )**

Operator \* (Premultiplication of vector by constant)

Returns

a\*x

**LocalVect< T\_, N\_ > operator/ ( T\_ a, const LocalVect< T\_, N\_ > & x )**

Operator / (Division of vector by constant)

Returns

x/a

**double Dot ( const LocalVect< T\_, N\_ > & a, const LocalVect< T\_, N\_ > & b )**

Calculate dot product of 2 vectors (instances of class [LocalVect](#))

Returns

Dot product

**Vect< T\_ > operator\* ( const SkMatrix< T\_ > & A, const Vect< T\_ > & b )**

Operator \* (Multiply vector by matrix and return resulting vector.

Parameters

in	A	<a href="#">SkMatrix</a> instance to multiply by vector
in	b	<a href="#">Vect</a> instance

Returns

[Vect](#) instance containing A\*b

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**ostream & operator<< ( ostream & s, const SkMatrix< T\_ > & a )**

Output matrix in output stream.

Author

Rachid Touzani

Copyright

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**Vect< T\_ > operator\* ( const SkSMatrix< T\_ > & A, const Vect< T\_ > & b )**

Operator \* (Multiply vector by matrix and return resulting vector.

Parameters

in	A	<a href="#">SkSMatrix</a> instance to multiply by vector
in	b	<a href="#">Vect</a> instance

Returns

[Vect](#) instance containing A\*b

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**ostream & operator<< ( ostream & s, const SkSMatrix< T\_ > & a )**

Output matrix in output stream.

Author

Rachid Touzani

Copyright

**Vect< T\_ > operator\* ( const SpMatrix< T\_ > & A, const Vect< T\_ > & b )**

Operator \* (Multiply vector by matrix and return resulting vector.

Parameters

in	A	<a href="#">SpMatrix</a> instance to multiply by vector
in	b	<a href="#">Vect</a> instance

Returns

[Vect](#) instance containing A\*b

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**ostream & operator<< ( ostream & s, const SpMatrix< T\_ > & A )**

Output matrix in output stream.

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**Vect< T\_ > operator\* ( const TrMatrix< T\_ > & A, const Vect< T\_ > & b )**

Operator \* (Multiply vector by matrix and return resulting vector.

Parameters

in	<i>A</i>	<a href="#">TrMatrix</a> instance to multiply by vector
in	<i>b</i>	<a href="#">Vect</a> instance

Returns

[Vect](#) instance containing  $A*b$

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**TrMatrix< T\_ > operator\* ( T\_ a, const TrMatrix< T\_ > & A )**

Operator \* (Premultiplication of matrix by constant)

Returns

$a*A$

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**ostream & operator<< ( ostream & s, const TrMatrix< T\_ > & a )**

Output matrix in output stream.

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**Vect< T\_ > operator+ ( const Vect< T\_ > & x, const Vect< T\_ > & y )**

Operator + (Addition of two instances of class Vect)

Returns

$$x + y$$

**Vect< T\_ > operator- ( const Vect< T\_ > & x, const Vect< T\_ > & y )**

Operator - (Difference between two vectors of class Vect)

Returns

$$x - y$$

**Vect< T\_ > operator\* ( const T\_ & a, const Vect< T\_ > & x )**

Operator \* (Premultiplication of vector by constant)

Returns

$$a*x$$

**Vect< T\_ > operator\* ( const Vect< T\_ > & x, const T\_ & a )**

Operator \* (Postmultiplication of vector by constant)

Returns

$$x*a$$

**Vect< T\_ > operator/ ( const Vect< T\_ > & x, const T\_ & a )**

Operator / (Divide vector entries by constant)

Returns

$$x/a$$

**T\_ Dot ( const Vect< T\_ > & x, const Vect< T\_ > & y )**

Calculate dot product of two vectors.

Returns

Dot (inner or scalar) product Calculate dot (scalar) product of two vectors

**void Modulus ( const Vect< complex\_t > & x, Vect< real\_t > & y )**

Calculate modulus of complex vector.

Parameters

in	$x$	Vector with complex value entries
out	$y$	Vector containing moduli of entries of $x$

**void Real ( const Vect< complex.t > &  $x$ , Vect< real.t > &  $y$  )**

Calculate real part of complex vector.

Parameters

in	$x$	Vector with complex value entries
out	$y$	Vector containing real parts of entries of $x$

**void Imag ( const Vect< complex.t > &  $x$ , Vect< real.t > &  $y$  )**

Calculate imaginary part of complex vector.

Parameters

in	$x$	Vector with complex value entries
out	$y$	Vector containing imaginary parts of entries of $x$

**istream & operator>> ( istream &  $s$ , Vect< T\_ > &  $a$  )**

Read vector from input stream

**ostream & operator<< ( ostream &  $s$ , const Vect< T\_ > &  $v$  )**

Output vector in output stream.

Level of vector output depends on the global variable `Verbosity`

- If `Verbosity=0`, this function outputs vector size only.
- If `Verbosity>0`, this function outputs vector size, vector name, value of time, and number of components
- If `Verbosity>1`, this function outputs in addition the first 10 entries in vector
- If `Verbosity>2`, this function outputs in addition the first 50 entries in vector
- If `Verbosity>3`, this function outputs in addition the first 100 entries in vector
- If `Verbosity>4`, this function outputs all vector entries

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**real.t operator\* ( const vector< real.t > &  $x$ , const vector< real.t > &  $y$  )**

Operator \* (Dot product of 2 vector instances)

Returns

$x \cdot y$

### 5.11.3 Friends

**ostream & operator<< ( ostream & s, const SpMatrix< TT\_ > & A ) [friend]**

Output matrix in output stream

## 5.12 Physical properties of media

Physical properties of materials and media.

Collaboration diagram for Physical properties of media:

### Classes

- class [Material](#)

*To treat material data. This class enables reading material data in material data files. It also returns these informations by means of its members.*

### 5.12.1 Detailed Description

Physical properties of materials and media.

## 5.13 Global Variables

All global variables in the library.

Collaboration diagram for Global Variables:

### Variables

- Node \* [theNode](#)  
*A pointer to [Node](#).*
- Element \* [theElement](#)  
*A pointer to [Element](#).*
- Side \* [theSide](#)  
*A pointer to [Side](#).*
- Edge \* [theEdge](#)  
*A pointer to [Edge](#).*
- int [Verbosity](#)  
*Verbosity parameter.*
- int [theStep](#)  
*Time step counter.*
- int [theIteration](#)  
*Iteration counter.*
- int [NbTimeSteps](#)  
*Number of time steps.*
- int [MaxNbIterations](#)  
*Maximal number of iterations.*
- real.t [theTimeStep](#)  
*Time step label.*
- real.t [theTime](#)  
*Time value.*
- real.t [theFinalTime](#)  
*Final time value.*
- real.t [theTolerance](#)  
*Tolerance value for convergence.*
- real.t [theDiscrepancy](#)  
*Value of discrepancy for an iterative procedure Its default value is 1. 0.*
- bool [Converged](#)  
*Boolean variable to say if an iterative procedure has converged.*
- bool [InitPetsc](#)

### 5.13.1 Detailed Description

All global variables in the library.

### 5.13.2 Variable Documentation

#### **Node\* theNode**

A pointer to [Node](#).

Useful for loops on nodes

#### **Element\* theElement**

A pointer to [Element](#).

Useful for loops on elements

#### **Side\* theSide**

A pointer to [Side](#).

Useful for loops on sides

#### **Edge\* theEdge**

A pointer to [Edge](#).

Useful for loops on edges

#### **int Verbosity**

Verbosity parameter.

Parameter for verbosity of message outputting.

The value of Verbosity can be modified anywhere in the calling programs. It allows outputting messages in function of the used class or function. To see how this parameter is used in any class, the [OFELI](#) user has to read corresponding documentation.

Its default value is 1

#### **int theStep**

Time step counter.

This counter must be initialized by the user if the macro `timeLoop` is not used

#### Remarks

May be used in conjunction with the macro `TimeLoop`. In this case, it has to be initialized before. Its default value is 1

#### **int theIteration**

Iteration counter.

This counter must be initialized by the user

#### Remarks

May be used in conjunction with the macro `IterationLoop`. Its default value is 1

**int NbTimeSteps**

Number of time steps.

Remarks

May be used in conjunction with the macro TimeLoop.

**int MaxNbIterations**

Maximal number of iterations.

Remarks

May be used in conjunction with the macro IterationLoop. Its default value is 1000

**real t theTimeStep**

Time step label.

Remarks

May be used in conjunction with the macro TimeLoop. In this case, it has to be initialized before

**real t theTime**

Time value.

Remarks

May be used in conjunction with the macro TimeLoop. Its default value is 0.0

**real t theFinalTime**

Final time value.

Remarks

May be used in conjunction with the macro TimeLoop. In this case, it has to be initialized before

**real t theTolerance**

Tolerance value for convergence.

Remarks

May be used within an iterative procedure. Its default value is 1.e-8

**bool Converged**

Boolean variable to say if an iterative procedure has converged.

Its default value is false

**bool InitPetsc**

Boolean to say if PETSc use was initialized. Useful only if PETSc is used

## 5.14 Finite Element Mesh

Mesh management classes

Collaboration diagram for Finite Element Mesh:

### Classes

- class [Domain](#)  
To store and treat finite element geometric information.
- class [Edge](#)  
To describe an edge.
- class [Element](#)  
To store and treat finite element geometric information.
- class [Figure](#)  
To store and treat a figure (or shape) information.
- class [Rectangle](#)  
To store and treat a rectangular figure.
- class [Brick](#)  
To store and treat a brick (parallelepiped) figure.
- class [Circle](#)  
To store and treat a circular figure.
- class [Sphere](#)  
To store and treat a sphere.
- class [Ellipse](#)  
To store and treat an ellipsoidal figure.
- class [Triangle](#)  
To store and treat a triangle.
- class [Polygon](#)  
To store and treat a polygonal figure.

- class [Grid](#)  
*To manipulate structured grids.*
- class [Mesh](#)  
*To store and manipulate finite element meshes.*
- class [MeshAdapt](#)  
*To adapt mesh in function of given solution.*
- class [NodeList](#)  
*Class to construct a list of nodes having some common properties.*
- class [ElementList](#)  
*Class to construct a list of elements having some common properties.*
- class [SideList](#)  
*Class to construct a list of sides having some common properties.*
- class [EdgeList](#)  
*Class to construct a list of edges having some common properties.*
- class [Node](#)  
*To describe a node.*
- class [Partition](#)  
*To partition a finite element mesh into balanced submeshes.*
- class [Side](#)  
*To store and treat finite element sides (edges in 2-D or faces in 3-D)*

## Macros

- `#define GRAPH\_MEMORY 1000000`  
*Memory necessary to store matrix graph.*
- `#define MAX\_NB\_ELEMENTS 10000`  
*Maximal Number of elements.*
- `#define MAX\_NB\_NODES 10000`  
*Maximal number of nodes.*
- `#define MAX\_NB\_SIDES 30000`  
*Maximal number of sides in.*
- `#define MAX\_NB\_EDGES 30000`  
*Maximal Number of edges.*
- `#define MAX\_NBDOF\_NODE 6`  
*Maximum number of DOF supported by each node.*
- `#define MAX\_NBDOF\_SIDE 6`  
*Maximum number of DOF supported by each side.*
- `#define MAX\_NBDOF\_EDGE 2`  
*Maximum number of DOF supported by each edge.*
- `#define MAX\_NB\_ELEMENT\_NODES 20`  
*Maximum number of nodes by element.*
- `#define MAX\_NB\_ELEMENT\_EDGES 10`  
*Maximum number of edges by element.*
- `#define MAX\_NB\_SIDE\_NODES 9`  
*Maximum number of nodes by side.*
- `#define MAX\_NB\_ELEMENT\_SIDES 8`  
*Maximum number of sides by element.*

- #define `MAX_NB_ELEMENT_DOF` 27  
*Maximum number of dof by element.*
- #define `MAX_NB_SIDE_DOF` 4  
*Maximum number of dof by side.*
- #define `MAX_NB_INT_PTS` 20  
*Maximum number of integration points in element.*
- #define `MAX_NB_MATERIALS` 10  
*Maximum number of materials.*
- #define `TheNode` (\*theNode)
- #define `TheElement` (\*theElement)
- #define `TheSide` (\*theSide)
- #define `TheEdge` (\*theEdge)

- #define `theSideLabel` theSide->n()  
*A macro that returns side label in a loop using macro `MeshSides`*
- #define `theSideNodeLabel`(i) theSide->getNodeLabel(i)  
*A macro that returns label of i-th node of side using macro `MeshSides`*
- #define `theElementLabel` theElement->n()  
*A macro that returns element label in a loop using macro `MeshElements`*
- #define `theElementNodeLabel`(i) theElement->getNodeLabel(i)  
*A macro that returns label of i-th node of element using macro `MeshElements`*

## Functions

- ostream & `operator<<` (ostream &s, const Edge &ed)  
*Output edge data.*
- ostream & `operator<<` (ostream &s, const Element &el)  
*Output element data.*
- Figure `operator&&` (const Figure &f1, const Figure &f2)  
*Function to define a `Figure` instance as the intersection of two `Figure` instances.*
- Figure `operator||` (const Figure &f1, const Figure &f2)  
*Function to define a `Figure` instance as the union of two `Figure` instances.*
- Figure `operator-` (const Figure &f1, const Figure &f2)  
*Function to define a `Figure` instance as the set subtraction of two `Figure` instances.*
- ostream & `operator<<` (ostream &s, const Material &m)  
*Output material data.*
- ostream & `operator<<` (ostream &s, const Mesh &ms)  
*Output mesh data.*
- ostream & `operator<<` (ostream &s, const MeshAdapt &a)

- Output *MeshAdapt* class data.

  - `ostream & operator<<` (`ostream &s`, `const NodeList &nl`)

Output *NodeList* instance.

  - `ostream & operator<<` (`ostream &s`, `const ElementList &el`)

Output *ElementList* instance.

  - `ostream & operator<<` (`ostream &s`, `const SideList &sl`)

Output *SideList* instance.

  - `ostream & operator<<` (`ostream &s`, `const EdgeList &el`)

Output *EdgeList* instance.

  - `size_t Label` (`const Node &nd`)

Return label of a given node.

  - `size_t Label` (`const Element &el`)

Return label of a given element.

  - `size_t Label` (`const Side &sd`)

Return label of a given side.

  - `size_t Label` (`const Edge &ed`)

Return label of a given edge.

  - `size_t NodeLabel` (`const Element &el`, `size_t n`)

Return global label of node local label in element.

  - `size_t NodeLabel` (`const Side &sd`, `size_t n`)

Return global label of node local label in side.

  - `Point< real_t > Coord` (`const Node &nd`)

Return coordinates of a given node.

  - `int Code` (`const Node &nd`, `size_t i=1`)

Return code of a given (degree of freedom of) node.

  - `int Code` (`const Element &el`)

Return code of a given element.

  - `int Code` (`const Side &sd`, `size_t i=1`)

Return code of a given (degree of freedom of) side.

  - `bool operator==` (`const Element &el1`, `const Element &el2`)

Check equality between 2 elements.

  - `bool operator==` (`const Side &sd1`, `const Side &sd2`)

Check equality between 2 sides.

  - `void DeformMesh` (`Mesh &mesh`, `const Vect< real_t > &u`, `real_t rate=0.2`)

Calculate deformed mesh using a displacement field.

  - `void MeshToMesh` (`Mesh &m1`, `Mesh &m2`, `const Vect< real_t > &u1`, `Vect< real_t > &u2`, `size_t nx`, `size_t ny=0`, `size_t nz=0`, `size_t dof=1`)

Function to redefine a vector defined on a mesh to a new mesh.

  - `void MeshToMesh` (`const Vect< real_t > &u1`, `Vect< real_t > &u2`, `size_t nx`, `size_t ny=0`, `size_t nz=0`, `size_t dof=1`)

Function to redefine a vector defined on a mesh to a new mesh.

  - `void MeshToMesh` (`Mesh &m1`, `Mesh &m2`, `const Vect< real_t > &u1`, `Vect< real_t > &u2`, `const Point< real_t > &xmin`, `const Point< real_t > &xmax`, `size_t nx`, `size_t ny`, `size_t nz`, `size_t dof=1`)

Function to redefine a vector defined on a mesh to a new mesh.

  - `real_t getMaxSize` (`const Mesh &m`)

Return maximal size of element edges for given mesh.

- `real_t getMinSize` (const Mesh &m)  
*Return minimal size of element edges for given mesh.*
- `real_t getMinElementMeasure` (const Mesh &m)  
*Return minimal measure (length, area or volume) of elements of given mesh.*
- `real_t getMaxElementMeasure` (const Mesh &m)  
*Return maximal measure (length, area or volume) of elements of given mesh.*
- `real_t getMinSideMeasure` (const Mesh &m)  
*Return minimal measure (length or area) of sides of given mesh.*
- `real_t getMaxSideMeasure` (const Mesh &m)  
*Return maximal measure (length or area) of sides of given mesh.*
- `real_t getMeanElementMeasure` (const Mesh &m)  
*Return average measure (length, area or volume) of elements of given mesh.*
- `real_t getMeanSideMeasure` (const Mesh &m)  
*Return average measure (length or area) of sides of given mesh.*
- void `setNodeCodes` (Mesh &m, const string &exp, int code, size\_t dof=1)  
*Assign a given code to all nodes satisfying a boolean expression using node coordinates.*
- void `setBoundaryNodeCodes` (Mesh &m, const string &exp, int code, size\_t dof=1)  
*Assign a given code to all nodes on boundary that satisfy a boolean expression using node coordinates.*
- int `NodeInElement` (const Node \*nd, const Element \*el)  
*Say if a given node belongs to a given element.*
- int `NodeInSide` (const Node \*nd, const Side \*sd)  
*Say if a given node belongs to a given side.*
- int `SideInElement` (const Side \*sd, const Element \*el)  
*Say if a given side belongs to a given element.*
- ostream & `operator<<` (ostream &s, const Node &nd)  
*Output node data.*
- ostream & `operator<<` (ostream &s, const Side &sd)  
*Output side data.*

### 5.14.1 Detailed Description

Mesh management classes

### 5.14.2 Macro Definition Documentation

**#define GRAPH\_MEMORY 1000000**

Memory necessary to store matrix graph.

This value is necessary only if nodes are to be renumbered.

**#define TheNode (\*theNode)**

A macro that gives the instance pointed by *theNode*

**#define TheElement (\*theElement)**

A macro that gives the instance pointed by *theElement*

**#define TheSide (\*theSide)**

A macro that gives the instance pointed by *theSide*

**#define TheEdge (\*theEdge)**

A macro that gives the instance pointed by *theEdge*

**#define ElementLoop( *m* ) for ((*m*).topElement(); (theElement=(*m*).getElement());**

A macro to loop on mesh elements *m* : Instance of Mesh

Note

: Each iteration updates the pointer *theElement* to current Element

**#define ActiveElementLoop( *m* ) for ((*m*).topElement(); (theElement=(*m*).getActiveElement());**

A macro to loop on mesh active elements *m* : Instance of Mesh

Note

: Each iteration updates the pointer *theElement* to current Element

: This macro is necessary only if adaptive meshing is used

**#define SideLoop( *m* ) for ((*m*).topSide(); (theSide=(*m*).getSide());**

A macro to loop on mesh sides *m* : Instance of Mesh

Note

: Each iteration updates the pointer *theSide* to current Element

**#define EdgeLoop( *m* ) for ((*m*).topEdge(); (theEdge=(*m*).getEdge());**

A macro to loop on mesh edges *m* : Instance of Mesh

Note

: Each iteration updates the pointer *theEdge* to current Edge

**#define NodeLoop( *m* ) for ((*m*).topNode(); (theNode=(*m*).getNode());**

A macro to loop on mesh nodes *m* : Instance of Mesh

Note

: Each iteration updates the pointer *theNode* to current Node

**#define BoundaryNodeLoop( *m* ) for ((*m*).topBoundaryNode(); (theNode=(*m*).getBoundaryNode());**

A macro to loop on mesh nodes *m*: Instance of Mesh

Note

: Each iteration updates the pointer *theNode* to current Node

```
#define BoundarySideLoop( m ) for ((m).topBoundarySide(); (theSide=(m).getBoundarySide());
```

A macro to loop on mesh boundary sides m: Instance of Mesh

Note

: Each iteration updates the pointer theSide to current Node

```
#define theNodeLabel theNode->n()
```

A macro that returns node label in a loop using macro *MeshNodes*

### 5.14.3 Function Documentation

**Figure operator&& ( const Figure & f1, const Figure & f2 )**

Function to define a [Figure](#) instance as the intersection of two [Figure](#) instances.

Parameters

in	<i>f1</i>	First <a href="#">Figure</a> instance
in	<i>f2</i>	Second <a href="#">Figure</a> instance

Returns

Updated resulting [Figure](#) instance

**Figure operator|| ( const Figure & f1, const Figure & f2 )**

Function to define a [Figure](#) instance as the union of two [Figure](#) instances.

Parameters

in	<i>f1</i>	First <a href="#">Figure</a> instance
in	<i>f2</i>	Second <a href="#">Figure</a> instance

Returns

Updated resulting [Figure](#) instance

**Figure operator- ( const Figure & f1, const Figure & f2 )**

Function to define a [Figure](#) instance as the set subtraction of two [Figure](#) instances.

Parameters

in	<i>f1</i>	First <a href="#">Figure</a> instance to subtract from
in	<i>f2</i>	Second <a href="#">Figure</a> instance to subtract

Returns

Updated resulting [Figure](#) instance

**ostream & operator<< ( ostream & s, const Mesh & ms )**

Output mesh data.

Level of mesh output depends on the global variable `Verbosity`

- If `Verbosity=0` or `Verbosity=1`, this function outputs only principal mesh parameters: number of nodes, number of elements, ...
- If `Verbosity>1`, this function outputs in addition the list of 10 first nodes, elements and sides
- If `Verbosity>2`, this function outputs in addition the list of 50 first nodes, elements and sides
- If `Verbosity>3`, this function outputs all mesh data

**ostream & operator<< ( ostream & s, const NodeList & nl )**

Output [NodeList](#) instance.

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**ostream & operator<< ( ostream & s, const ElementList & el )**

Output [ElementList](#) instance.

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**ostream & operator<< ( ostream & s, const SideList & sl )**

Output [SideList](#) instance.

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**ostream & operator<< ( ostream & s, const EdgeList & el )**

Output [EdgeList](#) instance.

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**size\_t Label ( const Node & *nd* )**

Return label of a given node.

## Parameters

<i>in</i>	<i>nd</i>	Reference to <a href="#">Node</a> instance
-----------	-----------	--

## Returns

Label of node

## Author

Rachid Touzani

## Copyright

GNU Lesser Public License

**size\_t Label ( const Element & *el* )**

Return label of a given element.

## Parameters

<i>in</i>	<i>el</i>	Reference to <a href="#">Element</a> instance
-----------	-----------	---

## Returns

Label of element

## Author

Rachid Touzani

## Copyright

GNU Lesser Public License

**size\_t Label ( const Side & *sd* )**

Return label of a given side.

## Parameters

<i>in</i>	<i>sd</i>	Reference to <a href="#">Side</a> instance
-----------	-----------	--

## Returns

Label of side

## Author

Rachid Touzani

## Copyright

GNU Lesser Public License

**size\_t Label ( const Edge & *ed* )**

Return label of a given edge.

Parameters

<b>in</b>	<i>ed</i>	Reference to <a href="#">Edge</a> instance
-----------	-----------	--

Returns

Label of edge

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**size\_t NodeLabel ( const Element & *el*, size\_t *n* )**

Return global label of node local label in element.

Parameters

<b>in</b>	<i>el</i>	Reference to <a href="#">Element</a> instance
<b>in</b>	<i>n</i>	Local label of node in element

Returns

Global label of node

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**size\_t NodeLabel ( const Side & *sd*, size\_t *n* )**

Return global label of node local label in side.

Parameters

<b>in</b>	<i>sd</i>	Reference to <a href="#">Side</a> instance
<b>in</b>	<i>n</i>	Local label of node in side

Returns

Global label of node

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**Point< real.t > Coord ( const Node & *nd* )**

Return coordinates of a given node.

## Parameters

<code>in</code>	<code>nd</code>	Reference to <a href="#">Node</a> instance
-----------------	-----------------	--

## Returns

Coordinates of node

## Author

Rachid Touzani

## Copyright

GNU Lesser Public License

**int Code ( const Node & *nd*, size\_t *i* = 1 )**

Return code of a given (degree of freedom of) node.

## Parameters

<code>in</code>	<code>nd</code>	Reference to <a href="#">Node</a> instance
<code>in</code>	<code>i</code>	Label of dof [Default: 1]

## Returns

Code of dof of node

## Author

Rachid Touzani

## Copyright

GNU Lesser Public License

**int Code ( const Element & *el* )**

Return code of a given element.

## Parameters

<code>in</code>	<code>el</code>	Reference to <a href="#">Element</a> instance
-----------------	-----------------	---

## Returns

Code of element

## Author

Rachid Touzani

## Copyright

GNU Lesser Public License

**int Code ( const Side & *sd*, size\_t *i* = 1 )**

Return code of a given (degree of freedom of) side.

## Parameters

<code>in</code>	<code>sd</code>	Reference to <a href="#">Side</a> instance
<code>in</code>	<code>i</code>	Label of dof [Default: 1]

## Returns

Code of dof of side

## Author

Rachid Touzani

## Copyright

GNU Lesser Public License

**operator== ( const Element & *el1*, const Element & *el2* )**

Check equality between 2 elements.

## Parameters

<code>in</code>	<code>el1</code>	Reference to first <a href="#">Side</a> instance
<code>in</code>	<code>el2</code>	Reference to second <a href="#">Side</a> instance

## Returns

true is elements are equal, *i.e.* if they have the same nodes, false if not.

## Author

Rachid Touzani

## Copyright

GNU Lesser Public License

**bool operator== ( const Side & *sd1*, const Side & *sd2* )**

Check equality between 2 sides.

## Parameters

<code>in</code>	<code>sd1</code>	Reference to first <a href="#">Side</a> instance
<code>in</code>	<code>sd2</code>	Reference to second <a href="#">Side</a> instance

## Returns

true is sides are equal, *i.e.* if they have the same nodes, false if not.

## Author

Rachid Touzani

## Copyright

GNU Lesser Public License

**void DeformMesh ( Mesh & *mesh*, const Vect< real.t > & *u*, real.t *a* = 0.2 )**

Calculate deformed mesh using a displacement field.

## Parameters

in,out	<i>mesh</i>	<a href="#">Mesh</a> instance. On output, node coordinates are modified to take into account the displacement
in	<i>u</i>	Displacement field at nodes
in	<i>a</i>	Maximal deformation rate. [Default: 1]. A typical value is 0.2 ( <i>i.e.</i> 20%).

## Author

Rachid Touzani

## Copyright

GNU Lesser Public License

```
void MeshToMesh ( Mesh & m1, Mesh & m2, const Vect< real.t > & u1, Vect< real.t > &
u2, size.t nx, size.t ny = 0, size.t nz = 0, size.t dof = 1 )
```

Function to redefine a vector defined on a mesh to a new mesh.

The program interpolates (piecewise linear) first the vector on a finer structured grid. Then the values on the new mesh nodes are computed.

## Remarks

For efficiency the number of grid cells must be large enough so that interpolation provides efficient accuracy

## Parameters

in	<i>m1</i>	Reference to the first mesh instance
out	<i>m2</i>	Reference to the second mesh instance
in	<i>u1</i>	Input vector of nodal values defined on first mesh
out	<i>u2</i>	Output vector of nodal values defined on second mesh
in	<i>nx</i>	Number of cells in the x-direction in the fine structured grid
in	<i>ny</i>	Number of cells in the y-direction in the fine structured grid The default value of ny is 0, i.e. a 1-D grid
in	<i>nz</i>	Number of cells in the z-direction in the fine structured grid The default value of nz is 0, i.e. a 1-D or 2-D grid
in	<i>dof</i>	Label of degree of freedom of vector u. Only this dof is considered. [Default: 1]

## Note

The input vector u1 is a one degree of freedom per node vector, i.e. its size must be equal (or greater than) the total number of nodes of mesh m1. The size of vector u2 is deduced from the mesh m2

## Author

Rachid Touzani

## Copyright

GNU Lesser Public License

```
void MeshToMesh ( const Vect< real.t > & u1, Vect< real.t > & u2, size.t nx, size.t ny = 0,  
size.t nz = 0, size.t dof = 1 )
```

Function to redefine a vector defined on a mesh to a new mesh.

The program interpolates (piecewise linear) first the vector on a finer structured grid. Then the values on the new mesh nodes are computed.

#### Remarks

For efficiency the number of grid cells must be large enough so that interpolation provides efficient accuracy

#### Parameters

in	<i>u1</i>	Input vector of nodal values defined on first mesh. This vector instance must contain <a href="#">Mesh</a> instance
out	<i>u2</i>	Output vector of nodal values defined on second mesh. This vector instance must contain <a href="#">Mesh</a> instance
in	<i>nx</i>	Number of cells in the x-direction in the fine structured grid
in	<i>ny</i>	Number of cells in the y-direction in the fine structured grid The default value of ny is 0, i.e. a 1-D grid
in	<i>nz</i>	Number of cells in the z-direction in the fine structured grid The default value of nz is 0, i.e. a 1-D or 2-D grid
in	<i>dof</i>	Label of degree of freedom of vector u. Only this dof is considered. [Default: 1]

#### Note

The input vector u1 is a one degree of freedom per node vector, i.e. its size must be equal (or greater than) the total number of nodes of mesh m1. The size of vector u2 is deduced from the mesh m2

#### Author

Rachid Touzani

#### Copyright

GNU Lesser Public License

```
void MeshToMesh ( Mesh & m1, Mesh & m2, const Vect< real.t > & u1, Vect< real.t > &  
u2, const Point< real.t > & xmin, const Point< real.t > & xmax, size.t nx, size.t ny, size.t  
nz, size.t dof = 1 )
```

Function to redefine a vector defined on a mesh to a new mesh.

The program interpolates (piecewise linear) first the vector on a finer structured grid. Then the values on the new mesh nodes are computed. In this function the grid rectangle is defined so that this one can cover only a submesh of m1.

#### Remarks

For efficiency the number of grid cells must be large enough so that interpolation provides efficient accuracy

## Parameters

in	<i>m1</i>	Reference to the first mesh instance
out	<i>m2</i>	Reference to the second mesh instance
in	<i>u1</i>	Input vector of nodal values defined on first mesh
out	<i>u2</i>	Output vector of nodal values defined on second mesh
in	<i>xmin</i>	<a href="#">Point</a> instance containing minimal coordinates of the rectangle that defines the grid
in	<i>xmax</i>	<a href="#">Point</a> instance containing maximal coordinates of the rectangle that defines the grid
in	<i>nx</i>	Number of cells in the x-direction in the fine structured grid
in	<i>ny</i>	Number of cells in the y-direction in the fine structured grid The default value of ny is 0, i.e. a 1-D grid
in	<i>nz</i>	Number of cells in the z-direction in the fine structured grid The default value of nz is 0, i.e. a 1-D or 2-D grid
in	<i>dof</i>	Label of degree of freedom of vector u. Only this dof is considered. [Default: 1]

## Note

The input vector *u1* is a one degree of freedom per node vector, i.e. its size must be equal (or greater than) the total number of nodes of mesh *m1*. The size of vector *u2* is deduced from the mesh *m2*

## Author

Rachid Touzani

## Copyright

GNU Lesser Public License

**real.t getMaxSize ( const Mesh & *m* )**

Return maximal size of element edges for given mesh.

## Parameters

in	<i>m</i>	Reference to mesh instance
----	----------	----------------------------

## Author

Rachid Touzani

## Copyright

GNU Lesser Public License

**real.t getMinSize ( const Mesh & *m* )**

Return minimal size of element edges for given mesh.

Parameters

<code>in</code>	<code>m</code>	Reference to mesh instance
-----------------	----------------	----------------------------

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**`real.t getMinElementMeasure ( const Mesh & m )`**

Return minimal measure (length, area or volume) of elements of given mesh.

Parameters

<code>in</code>	<code>m</code>	Reference to mesh instance
-----------------	----------------	----------------------------

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**`real.t getMaxElementMeasure ( const Mesh & m )`**

Return maximal measure (length, area or volume) of elements of given mesh.

Parameters

<code>in</code>	<code>m</code>	Reference to mesh instance
-----------------	----------------	----------------------------

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**`real.t getMinSideMeasure ( const Mesh & m )`**

Return minimal measure (length or area) of sides of given mesh.

Parameters

<code>in</code>	<code>m</code>	Reference to mesh instance
-----------------	----------------	----------------------------

Note

Use this function only if sides are present in the mesh and for 2-D meshes

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**real\_t getMaxSideMeasure ( const Mesh & *m* )**

Return maximal measure (length or area) of sides of given mesh.

## Parameters

<code>in</code>	<code>m</code>	Reference to mesh instance
-----------------	----------------	----------------------------

## Note

Use this function only if sides are present in the mesh and for 2-D meshes

## Author

Rachid Touzani

## Copyright

GNU Lesser Public License

**`real_t getMeanElementMeasure ( const Mesh & m )`**

Return average measure (length, area or volume) of elements of given mesh.

## Parameters

<code>in</code>	<code>m</code>	Reference to mesh instance
-----------------	----------------	----------------------------

## Author

Rachid Touzani

## Copyright

GNU Lesser Public License

**`real_t getMeanSideMeasure ( const Mesh & m )`**

Return average measure (length or area) of sides of given mesh.

## Parameters

<code>in</code>	<code>m</code>	Reference to mesh instance
-----------------	----------------	----------------------------

## Note

Use this function only if sides are present in the mesh and for 2-D meshes

## Author

Rachid Touzani

## Copyright

GNU Lesser Public License

**`void setNodeCodes ( Mesh & m, const string & exp, int code, size_t dof = 1 )`**

Assign a given code to all nodes satisfying a boolean expression using node coordinates.

Parameters

<code>in</code>	<code>m</code>	Reference to mesh instance
<code>in</code>	<code>exp</code>	Regular expression using <code>x</code> , <code>y</code> , and <code>z</code> coordinates of nodes, according to <code>exprtk</code> parser
<code>in</code>	<code>code</code>	Code to assign
<code>in</code>	<code>dof</code>	Degree of freedom for which code is assigned [Default: 1]

**void setBoundaryNodeCodes ( Mesh & *m*, const string & *exp*, int *code*, size\_t *dof* = 1 )**

Assign a given code to all nodes on boundary that satisfy a boolean expression using node coordinates.

Parameters

<code>in</code>	<code>m</code>	Reference to mesh instance
<code>in</code>	<code>exp</code>	Regular expression using <code>x</code> , <code>y</code> , and <code>z</code> coordinates of nodes, according to <code>exprtk</code> parser
<code>in</code>	<code>code</code>	Code to assign
<code>in</code>	<code>dof</code>	Degree of freedom for which code is assigned [Default: 1]

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**int NodeInElement ( const Node \* *nd*, const Element \* *el* )**

Say if a given node belongs to a given element.

Parameters

<code>in</code>	<code>nd</code>	Pointer to <a href="#">Node</a>
<code>in</code>	<code>el</code>	Pointer to <a href="#">Element</a>

Returns

Local label of the node if this one is found, 0 if not.

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**int NodeInSide ( const Node \* *nd*, const Side \* *sd* )**

Say if a given node belongs to a given side.

## Parameters

<code>in</code>	<code>nd</code>	Pointer to <a href="#">Node</a>
<code>in</code>	<code>sd</code>	Pointer to <a href="#">Side</a>

## Returns

Local label of the node if this one is found, 0 if not.

## Author

Rachid Touzani

## Copyright

GNU Lesser Public License

**int SideInElement ( const Side \* *sd*, const Element \* *el* )**

Say if a given side belongs to a given element.

## Parameters

<code>in</code>	<code>sd</code>	Pointer to <a href="#">Side</a>
<code>in</code>	<code>el</code>	Pointer to <a href="#">Element</a>

## Returns

Local label of the side if this one is found, 0 if not.

## Author

Rachid Touzani

## Copyright

GNU Lesser Public License

**ostream & operator<< ( ostream & *s*, const Node & *nd* )**

Output node data.

## Author

Rachid Touzani

## Copyright

GNU Lesser Public License

**ostream & operator<< ( ostream & *s*, const Side & *sd* )**

Output side data.

## 5.15 Shape Function

Shape function classes.

Collaboration diagram for Shape Function:

### Classes

- class [FEShape](#)  
*Parent class from which inherit all finite element shape classes.*
- class [triangle](#)  
*Defines a triangle. The reference element is the rectangle triangle with two unit edges.*
- class [Hexa8](#)  
*Defines a three-dimensional 8-node hexahedral finite element using  $Q_1$ -isoparametric interpolation.*
- class [Line2](#)  
*To describe a 2-Node planar line finite element.*
- class [Line3](#)  
*To describe a 3-Node quadratic planar line finite element.*
- class [Penta6](#)  
*Defines a 6-node pentahedral finite element using  $P_1$  interpolation in local coordinates  $(s.x, s.y)$  and  $Q_1$  isoparametric interpolation in local coordinates  $(s.x, s.z)$  and  $(s.y, s.z)$ .*
- class [Quad4](#)  
*Defines a 4-node quadrilateral finite element using  $Q_1$  isoparametric interpolation.*
- class [Tetra4](#)  
*Defines a three-dimensional 4-node tetrahedral finite element using  $P_1$  interpolation.*
- class [Triang3](#)  
*Defines a 3-Node ( $P_1$ ) triangle.*
- class [Triang6S](#)  
*Defines a 6-Node straight triangular finite element using  $P_2$  interpolation.*

### 5.15.1 Detailed Description

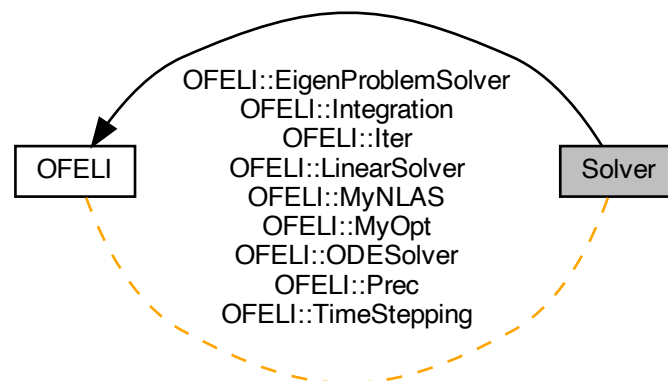

Shape function classes.

## 5.16 Solver

Solver functions and classes.

Collaboration diagram for Solver:

### Classes

- class [Reconstruction](#)  
*To perform various reconstruction operations.*
- class [EigenProblemSolver](#)  
*Class to find eigenvalues and corresponding eigenvectors of a given matrix in a generalized eigenproblem, i.e. Find scalars  $l$  and non-null vectors  $v$  such that  $[K]\{v\} = l[M]\{v\}$  where  $[K]$  and  $[M]$  are symmetric matrices. The eigenproblem can be originated from a PDE. For this, we will refer to the matrices  $K$  and  $M$  as Stiffness and Mass matrices respectively.*
- class [Integration](#)  
*Class for numerical integration methods.*
- class [Iter](#)< T\_ >  
*Class to drive an iterative process.*
- class [LinearSolver](#)< T\_ >  
*Class to solve systems of linear equations by iterative methods.*
- class [LPSolver](#)  
*To solve a linear programming problem.*
- class [MyNLAS](#)  
*Abstract class to define by user specified function.*
- class [MyOpt](#)  
*Abstract class to define by user specified optimization function.*
- class [NLASSolver](#)  
*To solve a system of nonlinear algebraic equations of the form  $f(u) = 0$ .*
- class [ODESolver](#)  
*To solve a system of ordinary differential equations.*

- class `OptSolver`  
*To solve an optimization problem with bound constraints.*
- class `Prec< T_ >`  
*To set a preconditioner.*
- class `TimeStepping`  
*To solve time stepping problems, i.e. systems of linear ordinary differential equations of the form  $[A2]\{y''\} + [A1]\{y'\} + [A0]\{y\} = \{b\}$ .*

## Macros

- `#define MAX_NB_INPUT_FIELDS 3`  
*Maximum number of fields for an equation.*
- `#define MAX_NB_MESHES 10`  
*Maximum number of meshes.*
- `#define TIME_LOOP(ts, t, ft, n)`  
*A macro to loop on time steps to integrate on time ts : Time step t : Initial time value updated at each time step ft : Final time value n : Time step index.*
- `#define TimeLoop`  
*A macro to loop on time steps to integrate on time.*
- `#define IterationLoop while (++theIteration<MaxNbIterations && Converged==false)`  
*A macro to loop on iterations for an iterative procedure.*

## Functions

- `ostream & operator<< (ostream &s, const Muscl3DT &m)`  
*Output mesh data as calculated in class `Muscl3DT`.*
- `template<class T_ >`  
`int BiCG (const SpMatrix< T_ > &A, const Prec< T_ > &P, const Vect< T_ > &b, Vect< T_ > &x, int max_it, real_t &toler)`  
*Biconjugate gradient solver function.*
- `template<class T_ >`  
`int BiCG (const SpMatrix< T_ > &A, int prec, const Vect< T_ > &b, Vect< T_ > &x, int max_it, real_t toler)`  
*Biconjugate gradient solver function.*
- `template<class T_ >`  
`int BiCGStab (const SpMatrix< T_ > &A, const Prec< T_ > &P, const Vect< T_ > &b, Vect< T_ > &x, int max_it, real_t toler)`  
*Biconjugate gradient stabilized solver function.*
- `template<class T_ >`  
`int BiCGStab (const SpMatrix< T_ > &A, int prec, const Vect< T_ > &b, Vect< T_ > &x, int max_it, real_t toler)`  
*Biconjugate gradient stabilized solver function.*
- `template<class T_ >`  
`int CG (const SpMatrix< T_ > &A, const Prec< T_ > &P, const Vect< T_ > &b, Vect< T_ > &x, int max_it, real_t toler)`  
*Conjugate gradient solver function.*
- `template<class T_ >`  
`int CG (const SpMatrix< T_ > &A, int prec, const Vect< T_ > &b, Vect< T_ > &x, int max_it, real_t toler)`

*Conjugate gradient solver function.*

- `template<class T_>`  
`int CGS (const SpMatrix< T_ > &A, const Prec< T_ > &P, const Vect< T_ > &b, Vect< T_ >`  
`&x, int max_it, real.t toler)`

*Conjugate Gradient Squared solver function.*

- `template<class T_>`  
`int CGS (const SpMatrix< T_ > &A, int prec, const Vect< T_ > &b, Vect< T_ > &x, int`  
`max_it, real.t toler)`

*Conjugate Gradient Squared solver function.*

- `ostream & operator<< (ostream &s, const EigenProblemSolver &es)`

*Output eigenproblem information.*

- `template<class T_>`  
`int GMRes (const SpMatrix< T_ > &A, const Prec< T_ > &P, const Vect< T_ > &b, Vect<`  
`T_ > &x, size.t m, int max_it, real.t toler)`

*GMRes solver function.*

- `template<class T_>`  
`int GMRes (const SpMatrix< T_ > &A, int prec, const Vect< T_ > &b, Vect< T_ > &x, size.t`  
`m, int max_it, real.t toler)`

*GMRes solver function.*

- `template<class T_>`  
`int GS (const SpMatrix< T_ > &A, const Vect< T_ > &b, Vect< T_ > &x, real.t omega, int`  
`max_it, real.t toler)`

*Gauss-Seidel solver function.*

- `template<class T_>`  
`int Jacobi (const SpMatrix< T_ > &A, const Vect< T_ > &b, Vect< T_ > &x, real.t omega,`  
`int max_it, real.t toler)`

*Jacobi solver function.*

- `ostream & operator<< (ostream &s, const LPSolver &os)`

*Output solver information.*

- `ostream & operator<< (ostream &s, const NLASSolver &nl)`

*Output nonlinear system information.*

- `ostream & operator<< (ostream &s, const ODESolver &de)`

*Output differential system information.*

- `ostream & operator<< (ostream &s, const OptSolver &os)`

*Output differential system information.*

- `template<class T_ , class M_ >`  
`int Richardson (const M_ &A, const Vect< T_ > &b, Vect< T_ > &x, real.t omega, int max_it,`  
`real.t toler, int verbose)`

*Richardson solver function.*

- `template<class T_>`  
`void Schur (SkMatrix< T_ > &A, SpMatrix< T_ > &U, SpMatrix< T_ > &L, SpMatrix< T_`  
`> &D, Vect< T_ > &b, Vect< T_ > &c)`

*Solve a linear system of equations with a 2x2-block matrix.*

- `template<class T_ , class M_ >`  
`int SSOR (const M_ &A, const Vect< T_ > &b, Vect< T_ > &x, int max_it, real.t toler)`

- `ostream & operator<< (ostream &s, TimeStepping &ts)`

*Output differential system information.*

### 5.16.1 Detailed Description

Solver functions and classes.

### 5.16.2 Macro Definition Documentation

#### **#define MAX\_NB\_INPUT\_FIELDS 3**

Maximum number of fields for an equation.  
Useful for coupled problems

#### **#define MAX\_NB\_MESHES 10**

Maximum number of meshes.  
Useful for coupled problems

#### **#define TimeLoop**

**Value:**

```
OFELI::NbTimeSteps = int(OFELI::theFinalTime/
    OFELI::theTimeStep); \
    for (OFELI::theTime=OFELI::theTimeStep,
        theStep=1; \
        theTime<OFELI::theFinalTime+0.001*
    OFELI::theTimeStep; \
        OFELI::theTime+=OFELI::theTimeStep, ++
    OFELI::theStep)
```

A macro to loop on time steps to integrate on time.

It uses the following global variables defined in **OFELI**: theStep, theTime, theTimeStep, theFinalTime

#### **#define IterationLoop while (++theIteration<MaxNbIterations && Converged==false)**

A macro to loop on iterations for an iterative procedure.

It uses the following global variables defined in **OFELI**: theIteration, MaxNbIterations, Converged

Warning

The variable theIteration must be zeroed before using this macro

### 5.16.3 Function Documentation

**int BiCG ( const SpMatrix< T\_ > & A, const Prec< T\_ > & P, const Vect< T\_ > & b, Vect< T\_ > & x, int max\_it, real\_t & toler )**

Biconjugate gradient solver function.

This function uses the preconditioned Biconjugate Conjugate Gradient algorithm to solve a linear system with a sparse matrix.

The global variable Verbosity enables choosing output message level

- Verbosity < 2 : No output message
- Verbosity > 1 : Notify executing the function BiCG
- Verbosity > 2 : Notify convergence with number of performed iterations or divergence
- Verbosity > 3 : Output each iteration number and residual

- Verbosity  $> 6$  : Print final solution if convergence
- Verbosity  $> 10$  : Print obtained solution at each iteration

## Parameters

in	$A$	Problem matrix (Instance of class <a href="#">SpMatrix</a> ).
in	$P$	Preconditioner (Instance of class <a href="#">Prec</a> ).
in	$b$	Right-hand side vector (class <a href="#">Vect</a> )
in, out	$x$	<a href="#">Vect</a> instance containing initial solution guess in input and solution of the linear system in output (If iterations have succeeded).
in	$max\_it$	Maximum number of iterations.
	$toler$	[in] Tolerance for convergence (measured in relative weighted 2-Norm).

## Returns

Number of performed iterations,

## Template Parameters

$\langle T\_ \rangle$	Data type (double, float, complex<double>, ...)
-----------------------	---

## Author

Rachid Touzani

GNU Lesser Public License

**int BiCG ( const [SpMatrix](#)< T\_ > & A, int *prec*, const [Vect](#)< T\_ > & b, [Vect](#)< T\_ > & x, int *max\_it*, real\_t *toler* )**

Biconjugate gradient solver function.

This function uses the preconditioned Biconjugate Conjugate Gradient algorithm to solve a linear system with a sparse matrix.

The global variable Verbosity enables choosing output message level

- Verbosity < 2 : No output message
- Verbosity > 1 : Notify executing the function CG
- Verbosity > 2 : Notify convergence with number of performed iterations or divergence
- Verbosity > 3 : Output each iteration number and residual
- Verbosity > 6 : Print final solution if convergence
- Verbosity > 10 : Print obtained solution at each iteration

## Parameters

in	$A$	Problem matrix (Instance of class <a href="#">SpMatrix</a> ).
in	$prec$	Enum variable selecting a preconditioner, among the values ID $\leftarrow$ ENT_PREC, DIAG_PREC, ILU_PREC or SSOR_PREC

<code>in</code>	<code>b</code>	Right-hand side vector (class <a href="#">Vect</a> )
<code>in,out</code>	<code>x</code>	<a href="#">Vect</a> instance containing initial solution guess in input and solution of the linear system in output (If iterations have succeeded).
<code>in</code>	<code>max_it</code>	Maximum number of iterations.
	<code>toler</code>	[in] Tolerance for convergence (measured in relative weighted 2-Norm).

## Returns

Number of performed iterations,

## Template Parameters

<code>&lt;T_&gt;</code>	Data type (double, float, complex<double>, ...)
-------------------------	---

## Author

Rachid Touzani

GNU Lesser Public License

**int BiCGStab ( const SpMatrix< T\_ > & A, const Prec< T\_ > & P, const Vect< T\_ > & b, Vect< T\_ > & x, int *max\_it*, real.t *toler* )**

Biconjugate gradient stabilized solver function.

This function uses the preconditioned Conjugate Gradient Stabilized algorithm to solve a linear system with a sparse matrix.

The global variable Verbosity enables choosing output message level

- Verbosity < 2 : No output message
- Verbosity > 1 : Notify executing the function BiCGStab
- Verbosity > 2 : Notify convergence with number of performed iterations or divergence
- Verbosity > 3 : Output each iteration number and residual
- Verbosity > 6 : Print final solution if convergence
- Verbosity > 10 : Print obtained solution at each iteration

## Parameters

<code>in</code>	<code>A</code>	Problem matrix (Instance of class <a href="#">SpMatrix</a> ).
<code>in</code>	<code>P</code>	Preconditioner (Instance of class <a href="#">Prec</a> ).
<code>in</code>	<code>b</code>	Right-hand side vector (class <a href="#">Vect</a> )
<code>in,out</code>	<code>x</code>	<a href="#">Vect</a> instance containing initial solution guess on input and solution of the linear system on output (If iterations have succeeded).

in	<i>max_it</i>	Maximum number of iterations.
in	<i>toler</i>	Tolerance for convergence (measured in relative weighted 2-↔ Norm).

## Returns

Number of performed iterations,

## Template Parameters

<T_>	Data type (double, float, complex<double>, ...)
------	---

**int BiCGStab ( const SpMatrix< T\_ > & A, int prec, const Vect< T\_ > & b, Vect< T\_ > & x, int max\_it, real.t toler )**

Biconjugate gradient stabilized solver function.

This function uses the preconditioned Conjugate Gradient Stabilized algorithm to solve a linear system with a sparse matrix.

The global variable Verbosity enables choosing output message level

- Verbosity < 2 : No output message
- Verbosity > 1 : Notify executing the function CG
- Verbosity > 2 : Notify convergence with number of performed iterations or divergence
- Verbosity > 3 : Output each iteration number and residual
- Verbosity > 6 : Print final solution if convergence
- Verbosity > 10 : Print obtained solution at each iteration

## Parameters

in	<i>A</i>	Problem matrix (Instance of class <a href="#">SpMatrix</a> ).
in	<i>prec</i>	Enum variable selecting a preconditioner, among the values ID↔ ENT_PREC, DIAG_PREC, ILU_PREC or SSOR_PREC
in	<i>b</i>	Right-hand side vector (class <a href="#">Vect</a> )
in,out	<i>x</i>	<a href="#">Vect</a> instance containing initial solution guess in input and solution of the linear system in output (If iterations have succeeded).
in	<i>max_it</i>	Maximum number of iterations.
in	<i>toler</i>	Tolerance for convergence (measured in relative weighted 2-↔ Norm).

## Returns

Number of performed iterations,

**int CG ( const SpMatrix< T\_ > & A, const Prec< T\_ > & P, const Vect< T\_ > & b, Vect< T\_ > & x, int max\_it, real\_t toler )**

Conjugate gradient solver function.

This function uses the preconditioned Conjugate Gradient algorithm to solve a linear system with a sparse matrix.

The global variable Verbosity enables choosing output message level

- Verbosity < 2 : No output message
- Verbosity > 1 : Notify executing the function CG
- Verbosity > 2 : Notify convergence with number of performed iterations or divergence
- Verbosity > 3 : Output each iteration number and residual
- Verbosity > 6 : Print final solution if convergence
- Verbosity > 10 : Print obtained solution at each iteration

## Parameters

in	$A$	Problem matrix (Instance of class <a href="#">SpMatrix</a> ).
in	$P$	Preconditioner (Instance of class <a href="#">Prec</a> ).
in	$b$	Right-hand side vector (class <a href="#">Vect</a> )
in,out	$x$	<a href="#">Vect</a> instance containing initial solution guess in input and solution of the linear system in output (If iterations have succeeded).
in	$max\_it$	Maximum number of iterations.
in	$toler$	Tolerance for convergence (measured in relative weighted 2- $\leftrightarrow$ Norm).

```
int CG ( const SpMatrix< T_ > & A, int prec, const Vect< T_ > & b, Vect< T_ > & x, int
max_it, real_t toler )
```

Conjugate gradient solver function.

This function uses the preconditioned Conjugate Gradient algorithm to solve a linear system with a sparse matrix.

The global variable Verbosity enables choosing output message level

- Verbosity < 2 : No output message
- Verbosity > 1 : Notify executing the function CG
- Verbosity > 2 : Notify convergence with number of performed iterations or divergence
- Verbosity > 3 : Output each iteration number and residual
- Verbosity > 6 : Print final solution if convergence
- Verbosity > 10 : Print obtained solution at each iteration

Parameters

in	<i>A</i>	Problem matrix (Instance of abstract class <a href="#">SpMatrix</a> ).
in	<i>prec</i>	Enum variable selecting a preconditioner, among the values ID↔ ENT_PREC, DIAG_PREC, ILU_PREC or SSOR_PREC
in	<i>b</i>	Right-hand side vector (class <a href="#">Vect</a> )
in,out	<i>x</i>	<a href="#">Vect</a> instance containing initial solution guess in input and solu- tion of the linear system in output (If iterations have succeeded).
in	<i>max_it</i>	Maximum number of iterations.
in	<i>toler</i>	Tolerance for convergence (measured in relative weighted 2-↔ Norm).

Returns

Number of performed iterations,

```
int CGS ( const SpMatrix< T_ > & A, const Prec< T_ > & P, const Vect< T_ > & b, Vect< T_ > & x, int max_it, real_t toler )
```

Conjugate Gradient Squared solver function.

This function uses the preconditioned Conjugate Gradient Squared algorithm to solve a linear system with a sparse matrix.

The global variable Verbosity enables choosing output message level

- Verbosity < 2 : No output message

- Verbosity > 1 : Notify executing the function CGS
- Verbosity > 2 : Notify convergence with number of performed iterations or divergence
- Verbosity > 3 : Output each iteration number and residual
- Verbosity > 6 : Print final solution if convergence
- Verbosity > 10 : Print obtained solution at each iteration

## Parameters

**int GMRes ( const SpMatrix< T\_ > & A, const Prec< T\_ > & P, const Vect< T\_ > & b, Vect< T\_ > & x, size\_t m, int max\_it, real\_t toler )**

GMRes solver function.

This function uses the preconditioned GMRES algorithm to solve a linear system with a sparse matrix.

The global variable Verbosity enables choosing output message level

- Verbosity < 2 : No output message
- Verbosity > 1 : Notify executing the function CMRes
- Verbosity > 2 : Notify convergence with number of performed iterations or divergence
- Verbosity > 3 : Output each iteration number and residual
- Verbosity > 6 : Print final solution if convergence
- Verbosity > 10 : Print obtained solution at each iteration

## Parameters

in	$A$	Problem matrix (Instance of class <a href="#">SpMatrix</a> ).
in	$P$	Preconditioner (Instance of class <a href="#">Prec</a> ).

in	$b$	Right-hand side vector (class <a href="#">Vect</a> )
in,out	$x$	<a href="#">Vect</a> instance containing initial solution guess in input and solution of the linear system in output (If iterations have succeeded).
in	$m$	Number of subspaces to generate for iterations.
in	$max\_it$	Maximum number of iterations.
in	$toler$	Tolerance for convergence (measured in relative weighted 2- $\leftrightarrow$ Norm).

## Returns

Number of performed iterations,

## Template Parameters

$\langle T\_ \rangle$	Data type (double, float, complex<double>, ...)

**int Richardson ( const  $M\_$  &  $A$ , const  $Vect< T\_ \rangle$  &  $b$ ,  $Vect< T\_ \rangle$  &  $x$ , real\_t  $\omega$ , int  $max\_it$ , real\_t  $toler$ , int  $verbose$  )**

Richardson solver function.

## Parameters

in	$A$	Problem matrix problem (Instance of abstract class $M\_$ ).
in	$b$	Right-hand side vector (class <a href="#">Vect</a> )
	$x$	<a href="#">Vect</a> instance containing initial solution guess in input and solution of the linear system in output (If iterations have succeeded).
in	$\omega$	Relaxation parameter.
in	$max\_it$	Maximum number of iterations.
in	$toler$	Tolerance for convergence (measured in relative weighted 2- $\leftrightarrow$ Norm).
in	$verbose$	Information output parameter (0: No output, 1: Output iteration information, 2 and greater: Output iteration information and solution at each iteration.

## Returns

$nb\_it$  Number of performed iterations,

## Template Parameters

<code>&lt;T_&gt;</code>	Data type (real_t, float, complex<real_t>, ...)
<code>&lt;M_&gt;</code>	Matrix storage class

## Author

**void Schur ( SkMatrix< T\_ > & A, SpMatrix< T\_ > & U, SpMatrix< T\_ > & L, SpMatrix< T\_ > & D, Vect< T\_ > & b, Vect< T\_ > & c )**

Solve a linear system of equations with a 2x2-block matrix.

The linear system is of the form

$$\begin{bmatrix} A & U \\ L & D \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} b \\ c \end{bmatrix}$$

## Parameters

in	$A$	Instance of class <a href="#">SkMatrix</a> class for the first diagonal block. The matrix must be invertible and factorizable (Do not use <a href="#">SpMatrix</a> class) where A, U, L, D are instances of matrix classes,
in	$U$	Instance of class <a href="#">SpMatrix</a> for the upper triangle block. The matrix can be rectangular
in	$L$	Instance of class <a href="#">SpMatrix</a> for the lower triangle block. The matrix can be rectangular
in	$D$	Instance of class <a href="#">SpMatrix</a> for the second diagonal block. The matrix must be factorizable (Do not use <a href="#">SpMatrix</a> class)
in,out	$b$	Vector (Instance of class <a href="#">Vect</a> ) that contains the first block of right-hand side on input and the first block of the solution on output. b must have the same size as the dimension of A.
in,out	$c$	<a href="#">Vect</a> instance that contains the second block of right-hand side on output and the first block of the solution on output. c must have the same size as the dimension of D.

## Template Argument:

## Template Parameters

<code>&lt;T_&gt;</code>	data type (real_t, float, ...)
-------------------------	--------------------------------

## Author

**int SSOR ( const M\_ & A, const Vect< T\_ > & b, Vect< T\_ > & x, int max\_it, real\_t toler )**

SSOR solver function.

## Parameters

in	$A$	Problem matrix (Instance of abstract class <b>M_</b> ).
in	$b$	Right-hand side vector (class <a href="#">Vect</a> )
in,out	$x$	<a href="#">Vect</a> instance containing initial solution guess in input and solution of the linear system in output (If iterations have succeeded).
in	$max\_it$	Maximum number of iterations.
in	$toler$	Tolerance for convergence (measured in relative weighted 2- $\leftrightarrow$ Norm).

## Returns

Number of performed iterations,

**Template Arguments:**

- $T_$  data type (double, float, ...)
- $M_$  Matrix storage class

## Classes

- class [LocalVect< T\\_, N\\_ >](#)
  - Handles small size vectors like element vectors.*
- class [ICPG1D](#)
  - Class to solve the Inviscid compressible fluid flows (Euler equations) for perfect gas in 1-D.*
- class [ICPG2DT](#)
  - Class to solve the Inviscid compressible fluid flows (Euler equations) for perfect gas in 2-D.*
- class [ICPG3DT](#)
  - Class to solve the Inviscid compressible fluid flows (Euler equations) for perfect gas in 3-D.*
- class [LCL1D](#)
  - Class to solve the linear conservation law (Hyperbolic equation) in 1-D by a MUSCL Finite Volume scheme.*
- class [LCL2DT](#)
  - Class to solve the linear hyperbolic equation in 2-D by a MUSCL Finite Volume scheme on triangles.*
- class [LCL3DT](#)
  - Class to solve the linear conservation law equation in 3-D by a MUSCL Finite Volume scheme on tetrahedra.*
- class [Muscl](#)
  - Parent class for hyperbolic solvers with Muscl scheme.*
- class [Vect< T\\_ >](#)
  - To handle general purpose vectors.*
- class [Muscl1D](#)
  - Class for 1-D hyperbolic solvers with [Muscl](#) scheme.*
- class [Muscl2DT](#)

- Class for 2-D hyperbolic solvers with [Muscl](#) scheme.*

  - class [Muscl3DT](#)
- Class for 3-D hyperbolic solvers with [Muscl](#) scheme using tetrahedra.*

  - class [BiotSavart](#)
- Class to compute the magnetic induction from the current density using the Biot-Savart formula.*

  - class [EC2D1T3](#)
- Eddy current problems in 2-D domains using solenoidal approximation.*

  - class [EC2D2T3](#)
- Eddy current problems in 2-D domains using transversal approximation.*

  - class [Equa.Electromagnetics< NEN\\_, NEE\\_, NSN\\_, NSE\\_ >](#)
- Abstract class for Electromagnetics [Equation](#) classes.*

  - class [HelmholtzBT3](#)
- Builds finite element arrays for Helmholtz equations in a bounded media using 3-Node triangles.*

  - class [Equa](#)
- Mother abstract class to describe equation.*

  - class [Equation< NEN\\_, NEE\\_, NSN\\_, NSE\\_ >](#)
- Abstract class for all equation classes.*

  - class [Equa.Fluid< NEN\\_, NEE\\_, NSN\\_, NSE\\_ >](#)
- Abstract class for Fluid Dynamics [Equation](#) classes.*

  - class [NSP2DQ41](#)
- Builds finite element arrays for incompressible Navier-Stokes equations in 2-D domains using  $Q_1/P_0$  element and a penalty formulation for the incompressibility condition.*

  - class [TINS2DT3S](#)
- Builds finite element arrays for transient incompressible fluid flow using Navier-Stokes equations in 2-D domains. Numerical approximation uses stabilized 3-node triangle finite elements for velocity and pressure. 2nd-order projection scheme is used for time integration.*

  - class [TINS3DT4S](#)
- Builds finite element arrays for transient incompressible fluid flow using Navier-Stokes equations in 3- $\leftrightarrow$  D domains. Numerical approximation uses stabilized 4-node tetrahedral finite elements for velocity and pressure. 2nd-order projection scheme is used for time integration.*

  - class [FastMarching](#)
- class for the fast marching algorithm on uniform grids*

  - class [FastMarching1DG](#)
- class for the fast marching algorithm on 1-D uniform grids*

  - class [FastMarching2DG](#)
- class for the fast marching algorithm on 2-D uniform grids*

  - class [FastMarching3DG](#)
- class for the fast marching algorithm on 3-D uniform grids*

  - class [Equa.Laplace< NEN\\_, NEE\\_, NSN\\_, NSE\\_ >](#)
- Abstract class for classes about the Laplace equation.*

  - class [Laplace1DL2](#)
- To build element equation for a 1-D elliptic equation using the 2-Node line element ( $P_1$ ).*

  - class [Laplace1DL3](#)
- To build element equation for the 1-D elliptic equation using the 3-Node line ( $P_2$ ).*

  - class [Laplace2DT3](#)
- To build element equation for the Laplace equation using the 2-D triangle element ( $P_1$ ).*

  - class [Laplace2DT6](#)
- To build element equation for the Laplace equation using the 2-D triangle element ( $P_2$ ).*

- class [SteklovPoincare2DBE](#)  
*Solver of the Steklov Poincare problem in 2-D geometries using piecewise constant boundary elemen.*
- class [Equa\\_Porous< NEN\\_, NEE\\_, NSN\\_, NSE\\_ >](#)  
*Abstract class for Porous Media Finite Element classes.*
- class [WaterPorous2D](#)  
*To solve water flow equations in porous media (1-D)*
- class [Bar2DL2](#)  
*To build element equations for Planar Elastic Bar element with 2 DOF (Degrees of Freedom) per node.*
- class [Beam3DL2](#)  
*To build element equations for 3-D beam equations using 2-node lines.*
- class [Elas2DQ4](#)  
*To build element equations for 2-D linearized elasticity using 4-node quadrilaterals.*
- class [Elas2DT3](#)  
*To build element equations for 2-D linearized elasticity using 3-node triangles.*
- class [Elas3DH8](#)  
*To build element equations for 3-D linearized elasticity using 8-node hexahedra.*
- class [Elas3DT4](#)  
*To build element equations for 3-D linearized elasticity using 4-node tetrahedra.*
- class [Equa\\_Solid< NEN\\_, NEE\\_, NSN\\_, NSE\\_ >](#)  
*Abstract class for Solid Mechanics Finite Element classes.*
- class [DC1DL2](#)  
*Builds finite element arrays for thermal diffusion and convection in 1-D using 2-Node elements.*
- class [DC2DT3](#)  
*Builds finite element arrays for thermal diffusion and convection in 2-D domains using 3-Node triangles.*
- class [DC2DT6](#)  
*Builds finite element arrays for thermal diffusion and convection in 2-D domains using 6-Node triangles.*
- class [DC3DAT3](#)  
*Builds finite element arrays for thermal diffusion and convection in 3-D domains with axisymmetry using 3-Node triangles.*
- class [DC3DT4](#)  
*Builds finite element arrays for thermal diffusion and convection in 3-D domains using 4-Node tetrahedra.*
- class [Equa\\_Therm< NEN\\_, NEE\\_, NSN\\_, NSE\\_ >](#)  
*Abstract class for Heat transfer Finite Element classes.*
- class [PhaseChange](#)  
*This class enables defining phase change laws for a given material.*
- class [Funct](#)  
*A simple class to parse real valued functions.*
- class [IOField](#)  
*Enables working with files in the XML Format.*
- class [IPF](#)  
*To read project parameters from a file in IPF format.*
- class [Prescription](#)  
*To prescribe various types of data by an algebraic expression. Data may consist in boundary conditions, forces, tractions, fluxes, initial condition. All these data types can be defined through an enumerated variable.*
- class [Tabulation](#)  
*To read and manipulate tabulated functions.*

- class [BMatrix< T\\_ >](#)  
*To handle band matrices.*
- class [DMatrix< T\\_ >](#)  
*To handle dense matrices.*
- class [DSMatrix< T\\_ >](#)  
*To handle symmetric dense matrices.*
- class [SkMatrix< T\\_ >](#)  
*To handle square matrices in skyline storage format.*
- class [SkSMatrix< T\\_ >](#)  
*To handle symmetric matrices in skyline storage format.*
- class [SpMatrix< T\\_ >](#)  
*To handle matrices in sparse storage format.*
- class [LocalMatrix< T\\_, NR\\_, NC\\_ >](#)  
*Handles small size matrices like element matrices, with a priori known size.*
- class [Matrix< T\\_ >](#)  
*Virtual class to handle matrices for all storage formats.*
- class [Point< T\\_ >](#)  
*Defines a point with arbitrary type coordinates.*
- class [Point2D< T\\_ >](#)  
*Defines a 2-D point with arbitrary type coordinates.*
- class [TrMatrix< T\\_ >](#)  
*To handle tridiagonal matrices.*
- class [Domain](#)  
*To store and treat finite element geometric information.*
- class [Edge](#)  
*To describe an edge.*
- class [Element](#)  
*To store and treat finite element geometric information.*
- class [Figure](#)  
*To store and treat a figure (or shape) information.*
- class [Rectangle](#)  
*To store and treat a rectangular figure.*
- class [Brick](#)  
*To store and treat a brick (parallelepiped) figure.*
- class [Circle](#)  
*To store and treat a circular figure.*
- class [Sphere](#)  
*To store and treat a sphere.*
- class [Ellipse](#)  
*To store and treat an ellipsoidal figure.*
- class [Triangle](#)  
*To store and treat a triangle.*
- class [Polygon](#)  
*To store and treat a polygonal figure.*
- class [Grid](#)  
*To manipulate structured grids.*

- class [Material](#)  
*To treat material data. This class enables reading material data in material data files. It also returns these informations by means of its members.*
- class [Mesh](#)  
*To store and manipulate finite element meshes.*
- class [MeshAdapt](#)  
*To adapt mesh in function of given solution.*
- class [NodeList](#)  
*Class to construct a list of nodes having some common properties.*
- class [ElementList](#)  
*Class to construct a list of elements having some common properties.*
- class [SideList](#)  
*Class to construct a list of sides having some common properties.*
- class [EdgeList](#)  
*Class to construct a list of edges having some common properties.*
- class [Node](#)  
*To describe a node.*
- class [Partition](#)  
*To partition a finite element mesh into balanced submeshes.*
- class [Side](#)  
*To store and treat finite element sides (edges in 2-D or faces in 3-D)*
- class [OFELIException](#)  
*To handle exceptions in [OFELI](#).*
- class [FEShape](#)  
*Parent class from which inherit all finite element shape classes.*
- class [triangle](#)  
*Defines a triangle. The reference element is the rectangle triangle with two unit edges.*
- class [Hexa8](#)  
*Defines a three-dimensional 8-node hexahedral finite element using  $Q_1$ -isoparametric interpolation.*
- class [Line2](#)  
*To describe a 2-Node planar line finite element.*
- class [Line3](#)  
*To describe a 3-Node quadratic planar line finite element.*
- class [Penta6](#)  
*Defines a 6-node pentahedral finite element using  $P_1$  interpolation in local coordinates  $(s.x, s.y)$  and  $Q_1$  isoparametric interpolation in local coordinates  $(s.x, s.z)$  and  $(s.y, s.z)$ .*
- class [Quad4](#)  
*Defines a 4-node quadrilateral finite element using  $Q_1$  isoparametric interpolation.*
- class [Tetra4](#)  
*Defines a three-dimensional 4-node tetrahedral finite element using  $P_1$  interpolation.*
- class [Triang3](#)  
*Defines a 3-Node ( $P_1$ ) triangle.*
- class [Triang6S](#)  
*Defines a 6-Node straight triangular finite element using  $P_2$  interpolation.*
- class [Prec< T\\_ >](#)  
*To set a preconditioner.*
- class [EigenProblemSolver](#)

*Class to find eigenvalues and corresponding eigenvectors of a given matrix in a generalized eigenproblem, i.e. Find scalars  $\lambda$  and non-null vectors  $v$  such that  $[K]\{v\} = \lambda[M]\{v\}$  where  $[K]$  and  $[M]$  are symmetric matrices. The eigenproblem can be originated from a PDE. For this, we will refer to the matrices  $K$  and  $M$  as Stiffness and Mass matrices respectively.*

- class [Integration](#)

*Class for numerical integration methods.*

- class [Iter< T\\_ >](#)

*Class to drive an iterative process.*

- class [LinearSolver< T\\_ >](#)

*Class to solve systems of linear equations by iterative methods.*

- class [MyNLAS](#)

*Abstract class to define by user specified function.*

- class [MyOpt](#)

*Abstract class to define by user specified optimization function.*

- class [ODESolver](#)

*To solve a system of ordinary differential equations.*

- class [TimeStepping](#)

*To solve time stepping problems, i.e. systems of linear ordinary differential equations of the form  $[A2]\{y''\} + [A1]\{y'\} + [A0]\{y\} = \{b\}$ .*

- class [Gauss](#)

*Calculate data for Gauss integration.*

- class [Timer](#)

*To handle elapsed time counting.*

## Enumerations

## Functions

- `T_ * A ()`  
*Return element matrix.*
- `T_ * b ()`  
*Return element right-hand side.*
- `T_ * Prev ()`  
*Return element previous vector.*
- `IOField ()`  
*Default constructor.*
- `IOField (const string &file, AccessType access, bool compact=true)`  
*Constructor using file name.*
- `IOField (const string &mesh.file, const string &file, Mesh &ms, AccessType access, bool compact=true)`  
*Constructor using file name, mesh file and mesh.*
- `IOField (const string &file, Mesh &ms, AccessType access, bool compact=true)`  
*Constructor using file name and mesh.*
- `IOField (const string &file, AccessType access, const string &name)`  
*Constructor using file name and field name.*
- `~IOField ()`  
*Destructor.*
- `void setMeshFile (const string &file)`  
*Set mesh file.*
- `void open ()`  
*Open file.*
- `void open (const string &file, AccessType access)`  
*Open file.*
- `void close ()`

- Close file.*
- `void put (Mesh &ms)`
  - Store mesh in file.*
- `void put (const Vect< real_t > &v)`
  - Store Vect instance v in file.*
- `real_t get (Vect< real_t > &v)`
  - Get Vect v instance from file.*
- `int get (Vect< real_t > &v, const string &name)`
  - Get Vect v instance from file if the field has the given name.*
- `int get (DMatrix< real_t > &A, const string &name)`
  - Get DMatrix A instance from file if the field has the given name.*
- `int get (DSMatrix< real_t > &A, const string &name)`
  - Get DSMatrix A instance from file if the field has the given name.*
- `int get (Vect< real_t > &v, real_t t)`
  - Get Vect v instance from file corresponding to a specific time value.*
- `void saveGMSH (string output_file, string mesh_file)`
  - Save field vectors in a file using GMSH format.*
- `Tabulation ()`
  - Default constructor.*
- `Tabulation (string file)`
  - Constructor using file name.*
- `~Tabulation ()`
  - Destructor.*
- `void setFile (string file)`
  - Set file name.*
- `real_t getValue (string funct, real_t x)`
  - Return the calculated value of the function.*
- `real_t getDerivative (string funct, real_t x)`
  - Return the derivative of the function at a given point.*
- `real_t getValue (string funct, real_t x, real_t y)`
  - Return the calculated value of the function.*
- `real_t getValue (string funct, real_t x, real_t y, real_t z)`
  - Return the calculated value of the function.*
- `real_t getValue (string funct, real_t x, real_t y, real_t z, real_t t)`
  - Return the calculated value of the function.*
- `size_t getNbFuncts () const`
  - Get the Number of read functions.*
- `size_t getNbVar (size_t n) const`
  - Get number of variables of a given function.*
- `string getFunctName (size_t n) const`
  - Get the name of a read function.*
- `size_t getSize (size_t n, size_t i) const`
  - Get number of points defining tabulation.*
- `real_t getMinVar (size_t n, size_t i) const`
  - Get minimal value of a variable.*
- `real_t getMaxVar (size_t n, size_t i) const`

- Get maximal value of a variable.*

  - `Point< real.t > CrossProduct (const Point< real.t > &lp, const Point< real.t > &rp)`  
*Return Cross product of two vectors lp and rp*
- `SpMatrix ()`  
*Default constructor.*
- `SpMatrix (size.t nr, size.t nc)`  
*Constructor that initializes current instance as a dense matrix.*
- `SpMatrix (size.t size, int is_diagonal=false)`  
*Constructor that initializes current instance as a dense matrix.*
- `SpMatrix (Mesh &mesh, size.t dof=0, int is_diagonal=false)`  
*Constructor using a Mesh instance.*
- `SpMatrix (const Vect< RC > &I, int opt=1)`  
*Constructor for a square matrix using non zero row and column indices.*
- `SpMatrix (const Vect< RC > &I, const Vect< T_ > &a, int opt=1)`  
*Constructor for a square matrix using non zero row and column indices.*
- `SpMatrix (size.t nr, size.t nc, const vector< size.t > &row_ptr, const vector< size.t > &col_ind)`  
*Constructor for a rectangle matrix.*
- `SpMatrix (size.t nr, size.t nc, const vector< size.t > &row_ptr, const vector< size.t > &col_ind, const vector< T_ > &a)`  
*Constructor for a rectangle matrix.*
- `SpMatrix (const vector< size.t > &row_ptr, const vector< size.t > &col_ind)`  
*Constructor for a rectangle matrix.*
- `SpMatrix (const vector< size.t > &row_ptr, const vector< size.t > &col_ind, const vector< T_ > &a)`  
*Constructor for a rectangle matrix.*
- `SpMatrix (const SpMatrix &m)`  
*Copy constructor.*
- `~SpMatrix ()`  
*Destructor.*
- `void Identity ()`  
*Define matrix as identity.*
- `void Dense ()`  
*Define matrix as a dense one.*
- `void Diagonal ()`  
*Define matrix as a diagonal one.*
- `void Diagonal (const T_ &a)`  
*Define matrix as a diagonal one with diagonal entries equal to a*
- `void Laplace1D (size.t n, real.t h)`  
*Sets the matrix as the one for the Laplace equation in 1-D.*
- `void Laplace2D (size.t nx, size.t ny)`  
*Sets the matrix as the one for the Laplace equation in 2-D.*
- `void setMesh (Mesh &mesh, size.t dof=0)`  
*Determine mesh graph and initialize matrix.*
- `void setOneDOF ()`  
*Activate 1-DOF per node option.*
- `void setSides ()`

*Activate Sides option.*

- void **setDiag** ()  
*Store diagonal entries in a separate internal vector.*
- void **DiagPrescribe** (Mesh &mesh, Vect< T\_ > &b, const Vect< T\_ > &u)  
*Impose by a diagonal method an essential boundary condition.*
- void **DiagPrescribe** (Vect< T\_ > &b, const Vect< T\_ > &u)  
*Impose by a diagonal method an essential boundary condition using the [Mesh](#) instance provided by the constructor.*
- void **setSize** (size\_t size)  
*Set size of matrix (case where it's a square matrix).*
- void **setSize** (size\_t nr, size\_t nc)  
*Set size (number of rows) of matrix.*
- void **setGraph** (const Vect< RC > &I, int opt=1)  
*Set graph of matrix by giving a vector of its nonzero entries.*
- Vect< T\_ > **getRow** (size\_t i) const  
*Get i-th row vector.*
- Vect< T\_ > **getColumn** (size\_t j) const  
*Get j-th column vector.*
- T\_ & **operator()** (size\_t i, size\_t j)  
*Operator () (Non constant version)*
- T\_ **operator()** (size\_t i, size\_t j) const  
*Operator () (Constant version)*
- T\_ **operator()** (size\_t i) const  
*Operator () with one argument (Constant version)*
- T\_ **operator[]** (size\_t i) const  
*Operator [] (Constant version).*
- Vect< T\_ > **operator\*** (const Vect< T\_ > &x) const  
*Operator \* to multiply matrix by a vector.*
- SpMatrix< T\_ > & **operator\*=** (const T\_ &a)  
*Operator \*= to premultiply matrix by a constant.*
- void **getMesh** (Mesh &mesh)  
*Get mesh instance whose reference will be stored in current instance of [SpMatrix](#).*
- void **Mult** (const Vect< T\_ > &x, Vect< T\_ > &y) const  
*Multiply matrix by vector and save in another one.*
- void **MultAdd** (const Vect< T\_ > &x, Vect< T\_ > &y) const  
*Multiply matrix by vector  $x$  and add to  $y$ .*
- void **MultAdd** (T\_ a, const Vect< T\_ > &x, Vect< T\_ > &y) const  
*Multiply matrix by vector  $a*x$  and add to  $y$ .*
- void **TMult** (const Vect< T\_ > &x, Vect< T\_ > &y) const  
*Multiply transpose of matrix by vector  $x$  and save in  $y$ .*
- void **Axpy** (T\_ a, const SpMatrix< T\_ > &m)  
*Add to matrix the product of a matrix by a scalar.*
- void **Axpy** (T\_ a, const Matrix< T\_ > \*m)  
*Add to matrix the product of a matrix by a scalar.*
- void **set** (size\_t i, size\_t j, const T\_ &val)  
*Assign a value to an entry of the matrix.*
- void **add** (size\_t i, size\_t j, const T\_ &val)

- Add a value to an entry of the matrix.*

  - void **operator=** (const T\_ &x)  
Operator =.
- size\_t **getColInd** (size\_t i) const  
*Return storage information.*
- size\_t **getRowPtr** (size\_t i) const  
*Return Row pointer at position i.*
- int **solve** (const Vect< T\_ > &b, Vect< T\_ > &x, bool fact=false)  
*Solve the linear system of equations.*
- void **setSolver** (Iteration solver=CG\_SOLVER, Preconditioner prec=DIAG\_PREC, int max←\_it=1000, real\_t toler=1.e-8)  
*Choose solver and preconditioner for an iterative procedure.*
- void **clear** ()  
*brief Set all matrix entries to zero*
- T\_ \* **get** () const  
*Return C-Array.*
- T\_ **get** (size\_t i, size\_t j) const  
*Return entry (i, j) of matrix if this one is stored, 0 otherwise.*
- **TrMatrix** ()  
*Default constructor.*
- **TrMatrix** (size\_t size)  
*Constructor for a tridiagonal matrix with size rows.*
- **TrMatrix** (const TrMatrix &m)  
*Copy Constructor.*
- **~TrMatrix** ()  
*Destructor.*
- void **Identity** ()  
*Define matrix as identity matrix.*
- void **Diagonal** ()  
*Define matrix as a diagonal one.*
- void **Diagonal** (const T\_ &a)  
*Define matrix as a diagona one and assign value a to all diagonal entries.*
- void **Laplace1D** (real\_t h)  
*Define matrix as the one of 3-point finite difference discretization of the second derivative.*
- void **setSize** (size\_t size)  
*Set size (number of rows) of matrix.*
- void **MultAdd** (const Vect< T\_ > &x, Vect< T\_ > &y) const  
*Multiply matrix by vector x and add result to y.*
- void **MultAdd** (T\_ a, const Vect< T\_ > &x, Vect< T\_ > &y) const  
*Multiply matrix by vector a\*x and add result to y.*
- void **Mult** (const Vect< T\_ > &x, Vect< T\_ > &y) const  
*Multiply matrix by vector x and save result in y.*
- void **TMult** (const Vect< T\_ > &x, Vect< T\_ > &y) const  
*Multiply transpose of matrix by vector x and save result in y.*
- void **Axpy** (T\_ a, const TrMatrix< T\_ > &m)  
*Add to matrix the product of a matrix by a scalar.*
- void **Axpy** (T\_ a, const Matrix< T\_ > \*m)

- Add to matrix the product of a matrix by a scalar.*

  - void **set** (size\_t i, size\_t j, const T\_ &val)  
*Assign constant val to an entry (i, j) of the matrix.*
  - void **add** (size\_t i, size\_t j, const T\_ &val)  
*Add constant val value to an entry (i, j) of the matrix.*
  - T\_ **operator()** (size\_t i, size\_t j) const  
*Operator () (Constant version).*
  - T\_ & **operator()** (size\_t i, size\_t j)  
*Operator () (Non constant version).*
  - TrMatrix< T\_ > & **operator=** (const TrMatrix< T\_ > &m)  
*Operator =.*
  - TrMatrix< T\_ > & **operator=** (const T\_ &x)  
*Operator = Assign matrix to identity times x.*
  - TrMatrix< T\_ > & **operator\*=** (const T\_ &x)  
*Operator \*.=.*
  - int **solve** (Vect< T\_ > &b, bool fact=true)  
*Solve a linear system with current matrix (forward and back substitution).*
  - int **solve** (const Vect< T\_ > &b, Vect< T\_ > &x, bool fact=false)  
*Solve a linear system with current matrix (forward and back substitution).*
  - T\_ \* **get** () const  
*Return C-Array.*
  - T\_ **get** (size\_t i, size\_t j) const  
*Return entry (i, j) of matrix.*
  - **Grid** ()  
*Construct a default grid with 10 intervals in each direction.*
  - **Grid** (real\_t xm, real\_t xM, size\_t npx)  
*Construct a 1-D structured grid given its extremal coordinates and number of intervals.*
  - **Grid** (real\_t xm, real\_t xM, real\_t ym, real\_t yM, size\_t npx, size\_t npy)  
*Construct a 2-D structured grid given its extremal coordinates and number of intervals.*
  - **Grid** (Point< real\_t > m, Point< real\_t > M, size\_t npx, size\_t npy)  
*Construct a 2-D structured grid given its extremal coordinates and number of intervals.*
  - **Grid** (real\_t xm, real\_t xM, real\_t ym, real\_t yM, real\_t zm, real\_t zM, size\_t npx, size\_t npy, size\_t npz)  
*Construct a 3-D structured grid given its extremal coordinates and number of intervals.*
  - **Grid** (Point< real\_t > m, Point< real\_t > M, size\_t npx, size\_t npy, size\_t npz)  
*Construct a 3-D structured grid given its extremal coordinates and number of intervals.*
  - void **setXMin** (const Point< real\_t > &x)  
*Set min. coordinates of the domain.*
  - void **setXMax** (const Point< real\_t > &x)
  - void **setDomain** (real\_t xmin, real\_t xmax)  
*Set Dimensions of the domain: 1-D case.*
  - void **setDomain** (real\_t xmin, real\_t xmax, real\_t ymin, real\_t ymax)  
*Set Dimensions of the domain: 2-D case.*
  - void **setDomain** (real\_t xmin, real\_t xmax, real\_t ymin, real\_t ymax, real\_t zmin, real\_t zmax)  
*Set Dimensions of the domain: 3-D case.*
  - void **setDomain** (Point< real\_t > xmin, Point< real\_t > xmax)  
*Set Dimensions of the domain: 3-D case.*

- `const Point< real.t > & getXMin () const`  
*Return min. Coordinates of the domain.*
- `const Point< real.t > & getXMax () const`  
*Return max. Coordinates of the domain.*
- `void setN (size.t nx, size.t ny=0, size.t nz=0)`  
*Set number of grid intervals in the x, y and z-directions.*
- `void setNbDOF (size.t n)`  
*Set number of degrees of freedom for a node [Default: 1].*
- `size.t getNx () const`  
*Return number of grid intervals in the x-direction.*
- `size.t getNy () const`  
*Return number of grid intervals in the y-direction.*
- `size.t getNz () const`  
*Return number of grid intervals in the z-direction.*
- `real.t getHx () const`  
*Return grid size in the x-direction.*
- `real.t getHy () const`  
*Return grid size in the y-direction.*
- `real.t getHz () const`  
*Return grid size in the z-direction.*
- `Point< real.t > getCoord (size.t i) const`  
*Return coordinates a point with label i in a 1-D grid.*
- `Point< real.t > getCoord (size.t i, size.t j) const`  
*Return coordinates a point with label (i, j) in a 2-D grid.*
- `Point< real.t > getCoord (size.t i, size.t j, size.t k) const`  
*Return coordinates a point with label (i, j, k) in a 3-D grid.*
- `size.t getNbNodes () const`  
*Return total number of grid nodes.*
- `size.t getNbDOF () const`  
*Return total number of dof.*
- `real.t getX (size.t i) const`  
*Return x-coordinate of point with index i*
- `real.t getY (size.t j) const`  
*Return y-coordinate of point with index j*
- `real.t getZ (size.t k) const`  
*Return z-coordinate of point with index k*
- `Point2D< real.t > getXY (size.t i, size.t j) const`  
*Return coordinates of point with indices (i, j)*
- `Point< real.t > getXYZ (size.t i, size.t j, size.t k) const`  
*Return coordinates of point with indices (i, j, k)*
- `real.t getCenter (size.t i) const`  
*Return coordinates of center of a 1-D cell with indices i, i+1*
- `Point< real.t > getCenter (size.t i, size.t j) const`  
*Return coordinates of center of a 2-D cell with indices (i, j), (i+1, j), (i+1, j+1), (i, j+1)*
- `Point< real.t > getCenter (size.t i, size.t j, size.t k) const`  
*Return coordinates of center of a 3-D cell with indices (i, j, k), (i+1, j, k), (i+1, j+1, k), (i, j+1, k), (i, j, k+1), (i+1, j, k+1), (i+1, j+1, k+1), (i, j+1, k+1)*

- void `setCode` (string exp, int code)  
*Set a code for some grid points.*
- void `setCode` (int side, int code)  
*Set a code for grid points on sides.*
- int `getCode` (int side) const  
*Return code for a side number.*
- int `getCode` (size\_t i, size\_t j) const  
*Return code for a grid point.*
- int `getCode` (size\_t i, size\_t j, size\_t k) const  
*Return code for a grid point.*
- size\_t `getDim` () const  
*Return space dimension.*
- void `Deactivate` (size\_t i)  
*Change state of a cell from active to inactive (1-D grid)*
- void `Deactivate` (size\_t i, size\_t j)  
*Change state of a cell from active to inactive (2-D grid)*
- void `Deactivate` (size\_t i, size\_t j, size\_t k)  
*Change state of a cell from active to inactive (2-D grid)*
- int `isActive` (size\_t i) const  
*Say if cell is active or not (1-D grid)*
- int `isActive` (size\_t i, size\_t j) const  
*Say if cell is active or not (2-D grid)*
- int `isActive` (size\_t i, size\_t j, size\_t k) const  
*Say if cell is active or not (3-D grid)*
- ostream & `operator<<` (ostream &s, const Grid &g)  
*Output grid data.*
- `OFELIException` (const std::string &s)  
*This form will be used most often in a throw.*
- `OFELIException` ()  
*Throw with no error message.*
- `Iter` ()  
*Default Constructor.*
- `Iter` (int max\_it, real\_t toler)  
*Constructor with iteration parameters.*
- bool `check` (Vect< T\_ > &u, const Vect< T\_ > &v, int opt=2)  
*Check convergence.*
- bool `check` (T\_ &u, const T\_ &v)  
*Check convergence for a scalar case (one equation)*

### 5.17.1 Detailed Description

### 5.17.2 Enumeration Type Documentation

#### enum PDE\_Terms

Enumerate variable that selects various terms in partial differential equations

Enumerator

`CONSISTENT_MASS` Consistent mass term

*LUMPED\_MASS* Lumped mass term  
*MASS* Consistent mass term  
*CAPACITY* Consistent capacity term  
*CONSISTENT\_CAPACITY* Consistent capacity term  
*LUMPED\_CAPACITY* Lumped capacity term  
*VISCOSITY* Viscosity term  
*STIFFNESS* Stiffness term  
*DIFFUSION* Diffusion term  
*MOBILITY* Mobility term  
*CONVECTION* Convection term  
*DEVIATORIC* Deviatoric term  
*DILATATION* Dilatational term  
*ELECTRIC* Electric term  
*MAGNETIC* Magnetic term  
*LOAD* Body load term  
*HEAT\_SOURCE* Body heat source term  
*BOUNDARY\_TRACTION* Boundary traction (pressure) term  
*HEAT\_FLUX* Boundary heat flux term  
*CONTACT* Signorini contact  
*BUOYANCY* Buoyancy force term  
*LORENTZ\_FORCE* Lorentz force term

#### **enum Analysis**

Selects Analysis type

Enumerator

*STATIONARY* Steady State analysis  
*STEADY\_STATE* Steady state analysis  
*TRANSIENT* Transient problem  
*TRANSIENT\_ONE\_STEP* Transient problem, perform only one time step  
*OPTIMIZATION* Optimization problem  
*EIGEN* Eigenvalue problem

#### **enum TimeScheme**

Selects Time integration scheme

Enumerator

*NONE* No time integration scheme  
*FORWARD\_EULER* Forward Euler scheme (Explicit)  
*BACKWARD\_EULER* Backward Euler scheme (Implicit)  
*CRANK\_NICOLSON* Crank-Nicolson scheme  
*HEUN* Heun scheme

**NEWMARK** Newmark scheme  
**LEAP\_FROG** Leap Frog scheme  
**ADAMS\_BASHFORTH** Adams-Bashforth scheme (2nd Order)  
**AB2** Adams-Bashforth scheme (2nd Order)  
**RUNGE\_KUTTA** 4-th Order Runge-Kutta scheme (4th Order)  
**RK4** 4-th Order Runge-Kutta scheme  
**RK3\_TVD** 3-rd Order Runge-Kutta TVD scheme  
**BDF2** Backward Difference Formula (2nd Order)  
**BUILTIN** Builtin scheme, implemented in equation class

#### enum FEType

Choose Finite [Element](#) Type

Enumerator

**FE\_2D\_3N** 2-D elements, 3-Nodes (P1)  
**FE\_2D\_6N** 2-D elements, 6-Nodes (P2)  
**FE\_2D\_4N** 2-D elements, 4-Nodes (Q1)  
**FE\_3D\_AXI\_3N** 3-D Axisymmetric elements, 3-Nodes (P1)  
**FE\_3D\_4N** 3-D elements, 4-Nodes (P1)  
**FE\_3D\_8N** 3-D elements, 8-Nodes (Q1)

#### enum MatrixType

Choose matrix storage and type

Enumerator

**DENSE** Dense storage  
**SKYLINE** Skyline storage  
**SPARSE** Sparse storage  
**DIAGONAL** Diagonal storage  
**TRIDIAGONAL** Tridiagonal storage  
**BAND** Band storage  
**SYMMETRIC** Symmetric matrix  
**UNSYMMETRIC** Unsymmetric matrix  
**IDENTITY** Identity matrix

#### enum Iteration

Choose iterative solver for the linear system.

Enumerator

**DIRECT\_SOLVER** Direct solver  
**CG\_SOLVER** CG Method  
**CGS\_SOLVER** CGS Method  
**BICG\_SOLVER** BiCG Method  
**BICG\_STAB\_SOLVER** BiCGStab Method  
**GMRES\_SOLVER** GMRes Method

**enum Preconditioner**

Choose preconditioner for the linear system.

Enumerator

*IDENT\_PREC* Identity (No preconditioning)  
*DIAG\_PREC* Diagonal preconditioner  
*DILU\_PREC* ILU (Incomplete factorization) preconditioner  
*ILU\_PREC* DILU (Diagonal Incomplete factorization) preconditioner  
*SSOR\_PREC* SSOR preconditioner

**enum BCType**

To select special boundary conditions.

Enumerator

*PERIODIC\_A* Periodic Boundary condition (first side)  
*PERIODIC\_B* Periodic Boundary condition (second side)  
*CONTACT\_BC* Contact Boundary conditions  
*CONTACT\_M* Contact Boundary condition, set as master side  
*CONTACT\_S* Contact Boundary condition, set as slave side  
*SLIP* Slip Boundary condition

**enum IntegrationScheme**

Choose numerical integration scheme

Enumerator

*LEFT\_RECTANGLE* Left rectangle integration formula  
*RIGHT\_RECTANGLE* Right rectangle integration formula  
*MID\_RECTANGLE* Midpoint (central) rectangle formula  
*TRAPEZOIDAL* Trapezoidal rule  
*SIMPSON* Simpson formula  
*GAUSS\_LEGENDRE* Gauss-Legendre quadrature formulae

**5.17.3 Function Documentation**

**T\_\* OFELI::A ( )**

Return element matrix.

Matrix is returned as a C-array

**T\_\* OFELI::b ( )**

Return element right-hand side.

Right-hand side is returned as a C-array

**T\_\* OFELI::Prev ( )**

Return element previous vector.

This is the vector given in time dependent constructor. It is returned as a C-array.

**IOField ( const string &file, AccessType access, bool compact = true )**

Constructor using file name.

Parameters

<code>in</code>	<i>file</i>	File name.
<code>in</code>	<i>access</i>	Access code. This number is to be chosen among two enumerated values: <ul style="list-style-type: none"> <li>• <code>IOField::IN</code> to read the file</li> <li>• <code>IOField::OUT</code> to write on it</li> </ul>
<code>in</code>	<i>compact</i>	Flag to choose a compact storage or not [Default: <code>true</code> ]

**IOField ( const string & mesh\_file, const string & file, Mesh & ms, AccessType access, bool compact = true )**

Constructor using file name, mesh file and mesh.

Parameters

<code>in</code>	<i>mesh_file</i>	File containing mesh
<code>in</code>	<i>file</i>	File that contains field stored or to store
<code>in</code>	<i>ms</i>	<a href="#">Mesh</a> instance
<code>in</code>	<i>access</i>	Access code. This number is to be chosen among two enumerated values: <ul style="list-style-type: none"> <li>• <code>IOField::IN</code> to read the file</li> <li>• <code>IOField::OUT</code> to write on it</li> </ul>
<code>in</code>	<i>compact</i>	Flag to choose a compact storage or not [Default: <code>true</code> ]

**IOField ( const string & file, Mesh & ms, AccessType access, bool compact = true )**

Constructor using file name and mesh.

Parameters

<code>in</code>	<i>file</i>	File that contains field stored or to store
<code>in</code>	<i>ms</i>	<a href="#">Mesh</a> instance
<code>in</code>	<i>access</i>	Access code. This number is to be chosen among two enumerated values: <ul style="list-style-type: none"> <li>• <code>IOField::IN</code> to read the file</li> <li>• <code>IOField::OUT</code> to write on it</li> </ul>

<b>in</b>	<i>compact</i>	Flag to choose a compact storage or not [Default: true]
-----------	----------------	---

### **IOField ( const string & file, AccessType access, const string & name )**

Constructor using file name and field name.

Parameters

<b>in</b>	<i>file</i>	File that contains field stored or to store
<b>in</b>	<i>access</i>	Access code. This number is to be chosen among two enumerated values: <ul style="list-style-type: none"> <li>• IOField::IN to read the file</li> <li>• IOField::OUT to write on it</li> </ul>
<b>in</b>	<i>name</i>	Seek a specific field with given <i>name</i>

### **void setMeshFile ( const string & file )**

Set mesh file.

Parameters

<b>in</b>	<i>file</i>	<a href="#">Mesh</a> file
-----------	-------------	---------------------------

### **void open ( )**

Open file.

Case where file name has been previously given (in the constructor).

### **void open ( const string & file, AccessType access )**

Open file.

Parameters

<b>in</b>	<i>file</i>	File name.
<b>in</b>	<i>access</i>	Access code. This number is to be chosen among two enumerated values: <ul style="list-style-type: none"> <li>• IOField::IN to read the file</li> <li>• IOField::OUT to write on it</li> </ul>

### **void put ( const Vect< real.t > & v )**

Store [Vect](#) instance v in file.

Parameters

<b>in</b>	<i>v</i>	<a href="#">Vect</a> instance to store
-----------	----------	--

**real\_t get ( Vect< real\_t > & v )**

Get [Vect](#) v instance from file.

First time step is read from the XML file.

**int get ( Vect< real\_t > & v, const string & name )**

Get [Vect](#) v instance from file if the field has the given name.

First time step is read from the XML file.

Parameters

in,out	<i>v</i>	<a href="#">Vect</a> instance
in	<i>name</i>	Name to seek in the XML file

**int get ( DMatrix< real\_t > & A, const string & name )**

Get [DMatrix](#) A instance from file if the field has the given name.

First time step is read from the XML file.

Parameters

in,out	<i>A</i>	<a href="#">DMatrix</a> instance
in	<i>name</i>	Name to seek in the XML file

**int get ( DSMatrix< real\_t > & A, const string & name )**

Get [DSMatrix](#) A instance from file if the field has the given name.

First time step is read from the XML file.

Parameters

in,out	<i>A</i>	<a href="#">DSMatrix</a> instance
in	<i>name</i>	Name to seek in the XML file

**int get ( Vect< real\_t > & v, real\_t t )**

Get [Vect](#) v instance from file corresponding to a specific time value.

The sought vector corresponding to the time value is read from the XML file.

Parameters

in,out	<i>v</i>	Vector instance
in	<i>t</i>	Time value

**void saveGMSH ( string output\_file, string mesh\_file )**

Save field vectors in a file using **GMSH** format.

This member function enables avoiding the use of `cfield`. It must be used once all field vectors have been stored in output file. It closes this file and copies its contents to a **GMSH** file.

Parameters

in	<i>output_file</i>	Output file name where to store using <b>GMSH</b> format
----	--------------------	--

<b>in</b>	<i>mesh_file</i>	File containing mesh data
-----------	------------------	---------------------------

**void setFile ( string *file* )**

Set file name.

This function is to be used when the default constructor is invoked.

**real.t getValue ( string *funct*, real.t *x* )**

Return the calculated value of the function.

Case of a function of one variable

Parameters

<b>in</b>	<i>funct</i>	Name of the function to be evaluated, as read from input file
<b>in</b>	<i>x</i>	Value of the variable

Returns

Computed value of the function

**real.t getDerivative ( string *funct*, real.t *x* )**

Return the derivative of the function at a given point.

Case of a function of one variable

Parameters

<b>in</b>	<i>funct</i>	Name of the function to be evaluated, as read from input file
<b>in</b>	<i>x</i>	Value of the variable

Returns

Derivative value

**real.t getValue ( string *funct*, real.t *x*, real.t *y* )**

Return the calculated value of the function.

Case of a function of two variables

Parameters

<b>in</b>	<i>funct</i>	Name of the function to be evaluated, as read from input file
<b>in</b>	<i>x</i>	Value of the first variable
<b>in</b>	<i>y</i>	Value of the second variable

Returns

Computed value of the function

**real.t getValue ( string *funct*, real.t *x*, real.t *y*, real.t *z* )**

Return the calculated value of the function.

Case of a function of three variables

## Parameters

in	<i>funct</i>	Name of the funct to be evaluated, as read from input file
in	<i>x</i>	Value of the first variable
in	<i>y</i>	Value of the second variable
in	<i>z</i>	Value of the third variable

## Returns

Computed value of the function

**real.t getValue ( string *funct*, real.t *x*, real.t *y*, real.t *z*, real.t *t* )**

Return the calculated value of the function.

Case of a function of three variables

## Parameters

in	<i>funct</i>	Name of the funct to be evaluated, as read from input file
in	<i>x</i>	Value of the first variable
in	<i>y</i>	Value of the second variable
in	<i>z</i>	Value of the third variable
in	<i>t</i>	Value of the fourth variable

## Returns

Computed value of the function

**size.t getNbFuncts ( ) const**

Get the Number of read functions.

## Returns

size.t Number of functions

**size.t getNbVar ( size.t *n* ) const**

Get number of variables of a given function.

## Parameters

in	<i>n</i>	index of function
----	----------	-------------------

## Returns

Number of variables

**string getFuncName ( size.t *n* ) const**

Get the name of a read function.

Parameters

<code>in</code>	<code>n</code>	index of function
-----------------	----------------	-------------------

Returns

Name of function

**size.t getSize ( size.t *n*, size.t *i* ) const**

Get number of points defining tabulation.

Parameters

<code>in</code>	<code>n</code>	index of function (Starting from 1)
<code>in</code>	<code>i</code>	index of variable (Between 1 and 3)

Returns

Size

**real.t getMinVar ( size.t *n*, size.t *i* ) const**

Get minimal value of a variable.

Parameters

<code>in</code>	<code>n</code>	index of function
<code>in</code>	<code>i</code>	index of variable (Between 1 and 3)

Returns

Minimal value

**real.t getMaxVar ( size.t *n*, size.t *i* ) const**

Get maximal value of a variable.

Parameters

<code>in</code>	<code>n</code>	index of function
<code>in</code>	<code>i</code>	index of variable (between 1 and 3)

Returns

**SpMatrix ( )**

Default constructor.

Initialize a zero-dimension matrix

**SpMatrix ( size.t *nr*, size.t *nc* )**

Constructor that initializes current instance as a dense matrix.

Normally, for a dense matrix this is not the right class.

Parameters

<code>in</code>	<code>nr</code>	Number of matrix rows.
<code>in</code>	<code>nc</code>	Number of matrix columns.

**SpMatrix ( `size_t size`, `int is_diagonal = false` )**

Constructor that initializes current instance as a dense matrix.

Normally, for a dense matrix this is not the right class.

Parameters

<code>in</code>	<code>size</code>	Number of matrix rows (and columns).
<code>in</code>	<code>is_diagonal</code>	Boolean argument to say is the matrix is actually a diagonal matrix or not.

**SpMatrix ( `Mesh & mesh`, `size_t dof = 0`, `int is_diagonal = false` )**

Constructor using a [Mesh](#) instance.

Parameters

<code>in</code>	<code>mesh</code>	<a href="#">Mesh</a> instance from which matrix graph is extracted.
<code>in</code>	<code>dof</code>	Option parameter, with default value 0. dof=1 means that only one degree of freedom for each node (or element or side) is taken to determine matrix structure. The value dof=0 means that matrix structure is determined using all DOFs.
<code>in</code>	<code>is_diagonal</code>	Boolean argument to say is the matrix is actually a diagonal matrix or not.

**SpMatrix ( `const Vect< RC > & I`, `int opt = 1` )**

Constructor for a square matrix using non zero row and column indices.

Parameters

<code>in</code>	<code>I</code>	Vector containing pairs of row and column indices
<code>in</code>	<code>opt</code>	Flag indicating if vectors I is cleaned and ordered (opt=1) or not (opt=0). In the latter case, this vector can have the same contents more than once and are not necessarily ordered

**SpMatrix ( `const Vect< RC > & I`, `const Vect< T_ > & a`, `int opt = 1` )**

Constructor for a square matrix using non zero row and column indices.

Parameters

<code>in</code>	<code>I</code>	Vector containing pairs of row and column indices
<code>in</code>	<code>a</code>	Vector containing matrix entries in the same order than the one given by I
<code>in</code>	<code>opt</code>	Flag indicating if vector I is cleaned and ordered (opt=1: default) or not (opt=0). In the latter case, this vector can have the same contents more than once and are not necessarily ordered

**SpMatrix** ( *size\_t nr*, *size\_t nc*, *const vector< size\_t > & row\_ptr*, *const vector< size\_t > & col\_ind* )

Constructor for a rectangle matrix.

Parameters

<b>in</b>	<i>nr</i>	Number of rows
<b>in</b>	<i>nc</i>	Number of columns
<b>in</b>	<i>row_ptr</i>	Vector of row pointers (See the above description of this class).
<b>in</b>	<i>col_ind</i>	Vector of column indices (See the above description of this class).

**SpMatrix ( size\_t nr, size\_t nc, const vector< size\_t > & row\_ptr, const vector< size\_t > & col\_ind, const vector< T\_ > & a )**

Constructor for a rectangle matrix.

Parameters

<b>in</b>	<i>nr</i>	Number of rows
<b>in</b>	<i>nc</i>	Number of columns
<b>in</b>	<i>row_ptr</i>	Vector of row pointers (See the above description of this class).
<b>in</b>	<i>col_ind</i>	Vector of column indices (See the above description of this class).
<b>in</b>	<i>a</i>	vector instance containing matrix entries stored columnwise

**SpMatrix ( const vector< size\_t > & row\_ptr, const vector< size\_t > & col\_ind )**

Constructor for a rectangle matrix.

Parameters

<b>in</b>	<i>row_ptr</i>	Vector of row pointers (See the above description of this class).
<b>in</b>	<i>col_ind</i>	Vector of column indices (See the above description of this class).

**SpMatrix ( const vector< size\_t > & row\_ptr, const vector< size\_t > & col\_ind, const vector< T\_ > & a )**

Constructor for a rectangle matrix.

Parameters

<b>in</b>	<i>row_ptr</i>	Vector of row pointers (See the above description of this class).
<b>in</b>	<i>col_ind</i>	Vector of column indices (See the above description of this class).
<b>in</b>	<i>a</i>	vector instance that contain matrix entries stored row by row. Number of rows is extracted from vector row_ptr.

**void Laplace1D ( size\_t n, real\_t h )**

Sets the matrix as the one for the Laplace equation in 1-D.

The matrix is initialized as the one resulting from  $P_1$  finite element discretization of the classical elliptic operator  $-u'' = f$  with homogeneous Dirichlet boundary conditions

Remarks

This function is available for real valued matrices only.

Parameters

<code>in</code>	<code>n</code>	Size of matrix (Number of rows)
<code>in</code>	<code>h</code>	Mesh size (assumed constant)

**void Laplace2D ( `size.t nx`, `size.t ny` )**

Sets the matrix as the one for the Laplace equation in 2-D.

The matrix is initialized as the one resulting from  $P_1$  finite element discretization of the classical elliptic operator  $-\Delta u = f$  with homogeneous Dirichlet boundary conditions

Remarks

This function is available for real valued matrices only.

Parameters

<code>in</code>	<code>nx</code>	Number of unknowns in the x-direction
<code>in</code>	<code>ny</code>	Number of unknowns in the y-direction

Remarks

The number of rows is equal to `nx*ny`

**void setMesh ( `Mesh & mesh`, `size.t dof = 0` )**

Determine mesh graph and initialize matrix.

This member function is called by constructor with the same arguments

Parameters

<code>in</code>	<code>mesh</code>	<a href="#">Mesh</a> instance for which matrix graph is determined.
<code>in</code>	<code>dof</code>	Option parameter, with default value 0. dof=1 means that only one degree of freedom for each node (or element or side) is taken to determine matrix structure. The value dof=0 means that matrix structure is determined using all DOFs.

**void DiagPrescribe ( `Mesh & mesh`, `Vect< T_ > & b`, `const Vect< T_ > & u` )**

Impose by a diagonal method an essential boundary condition.

This member function modifies diagonal terms in matrix and terms in vector that correspond to degrees of freedom with nonzero code in order to impose a boundary condition. The penalty parameter is defined by default equal to  $1.e20$ . It can be modified by member function `setPenal(..)`.

Parameters

<code>in</code>	<code>mesh</code>	<a href="#">Mesh</a> instance from which information is extracted.
<code>in,out</code>	<code>b</code>	<a href="#">Vect</a> instance that contains right-hand side.
<code>in</code>	<code>u</code>	<a href="#">Vect</a> instance that contains imposed values at DOFs where they are to be imposed.

**void DiagPrescribe ( Vect< T\_ > & b, const Vect< T\_ > & u )**

Impose by a diagonal method an essential boundary condition using the [Mesh](#) instance provided by the constructor.

This member function modifies diagonal terms in matrix and terms in vector that correspond to degrees of freedom with nonzero code in order to impose a boundary condition. The penalty parameter is defined by default equal to 1.e20. It can be modified by member function **setPenal(..)**.

Parameters

in,out	<i>b</i>	<a href="#">Vect</a> instance that contains right-hand side.
in	<i>u</i>	<a href="#">Vect</a> instance that contains imposed values at DOFs where they are to be imposed.

**void setSize ( size\_t size )**

Set size of matrix (case where it's a square matrix).

Parameters

in	<i>size</i>	Number of rows and columns.
----	-------------	-----------------------------

**void setSize ( size\_t nr, size\_t nc )**

Set size (number of rows) of matrix.

Parameters

in	<i>nr</i>	Number of rows
in	<i>nc</i>	Number of columns

**void setGraph ( const Vect< RC > & I, int opt = 1 )**

Set graph of matrix by giving a vector of its nonzero entries.

Parameters

in	<i>I</i>	Vector containing pairs of row and column indices
in	<i>opt</i>	Flag indicating if vector I is cleaned and ordered (opt=1: default) or not (opt=0). In the latter case, this vector can have the same contents more than once and are not necessarily ordered

**T\_& operator() ( size\_t i, size\_t j ) [virtual]**

Operator () (Non constant version)

Parameters

in	<i>i</i>	Row index
in	<i>j</i>	Column index

Implements [Matrix< T\\_ >](#).

**T\_ operator() ( size\_t i, size\_t j ) const [virtual]**

Operator () (Constant version)

Parameters

in	<i>i</i>	Row index
in	<i>j</i>	Column index

Implements [Matrix< T\\_ >](#).

**T\_ operator() ( size\_t i ) const**

Operator () with one argument (Constant version)

Returns i-th position in the array storing matrix entries. The first entry is at location 1. Entries are stored row by row.

**T\_ operator[] ( size\_t i ) const**

Operator [] (Constant version).

Returns i-th position in the array storing matrix entries. The first entry is at location 0. Entries are stored row by row.

**Vect<T\_> operator\* ( const Vect< T\_ > & x ) const**

Operator \* to multiply matrix by a vector.

Parameters

in	<i>x</i>	<a href="#">Vect</a> instance to multiply by
----	----------	--

Returns

Vector product of matrix by x

**SpMatrix<T\_>& operator\*= ( const T\_ & a )**

Operator \*= to premultiply matrix by a constant.

Parameters

in	<i>a</i>	Constant to multiply matrix by
----	----------	--------------------------------

Returns

Resulting matrix

**void Mult ( const Vect< T\_ > & x, Vect< T\_ > & y ) const [virtual]**

Multiply matrix by vector and save in another one.

Parameters

in	<i>x</i>	Vector to multiply by matrix
out	<i>y</i>	Vector that contains on output the result.

Implements [Matrix< T\\_ >](#).

**void MultAdd ( const Vect< T\_ > & x, Vect< T\_ > & y ) const [virtual]**

Multiply matrix by vector x and add to y.

Parameters

in	$x$	Vector to multiply by matrix
out	$y$	Vector to add to the result. $y$ contains on output the result.

Implements [Matrix< T\\_ >](#).

**void MultAdd ( T\_  $a$ , const Vect< T\_ > &  $x$ , Vect< T\_ > &  $y$  ) const** [virtual]

Multiply matrix by vector  $a*x$  and add to  $y$ .

Parameters

in	$a$	Constant to multiply by matrix
in	$x$	Vector to multiply by matrix
out	$y$	Vector to add to the result. $y$ contains on output the result.

Implements [Matrix< T\\_ >](#).

**void TMult ( const Vect< T\_ > &  $x$ , Vect< T\_ > &  $y$  ) const** [virtual]

Multiply transpose of matrix by vector  $x$  and save in  $y$ .

Parameters

in	$x$	Vector to multiply by matrix
out	$y$	Vector that contains on output the result.

Implements [Matrix< T\\_ >](#).

**void Axy ( T\_  $a$ , const SpMatrix< T\_ > &  $m$  )**

Add to matrix the product of a matrix by a scalar.

Parameters

in	$a$	Scalar to premultiply
in	$m$	Matrix by which $a$ is multiplied. The result is added to current instance

**void Axy ( T\_  $a$ , const Matrix< T\_ > \*  $m$  )** [virtual]

Add to matrix the product of a matrix by a scalar.

Parameters

in	$a$	Scalar to premultiply
in	$m$	Pointer to <a href="#">Matrix</a> by which $a$ is multiplied. The result is added to current instance

Implements [Matrix< T\\_ >](#).

**void set ( size\_t  $i$ , size\_t  $j$ , const T\_ &  $val$  )** [virtual]

Assign a value to an entry of the matrix.

Parameters

in	$i$	Row index
in	$j$	Column index
in	$val$	Value to assign to $a(i, j)$

Implements [Matrix< T\\_ >](#).

**void add ( size\_t *i*, size\_t *j*, const T\_ & *val* )** [virtual]

Add a value to an entry of the matrix.

Parameters

in	<i>i</i>	Row index
in	<i>j</i>	Column index
in	<i>val</i>	Constant value to add to $a(i, j)$

Implements [Matrix< T\\_ >](#).

**void operator= ( const T\_ & x )**

Operator =.

Assign constant value x to all matrix entries.

**size\_t getColInd ( size\_t i ) const** [virtual]

Return storage information.

Returns

Column index of the i-th stored element in matrix

Reimplemented from [Matrix< T\\_ >](#).

**int solve ( const Vect< T\_ > & b, Vect< T\_ > & x, bool fact = false )** [virtual]

Solve the linear system of equations.

The default parameters are:

- CG\_SOLVER for solver
- DIAG\_PREC for preconditioner
- Max. Number of iterations is 1000
- Tolerance is  $1.e-8$

To change these values, call function setSolver before this function

Parameters

in	<i>b</i>	Vector that contains right-hand side
out	<i>x</i>	Vector that contains the obtained solution
in	<i>fact</i>	Unused argument

Returns

Number of actual performed iterations

Implements [Matrix< T\\_ >](#).

**void setSolver ( Iteration solver = CG\_SOLVER, Preconditioner prec = DIAG\_PREC, int max\_it = 1000, real\_t toler =  $1.e-8$  )**

Choose solver and preconditioner for an iterative procedure.

Parameters

in	<i>solver</i>	Option to choose iterative solver in an enumerated variable <ul style="list-style-type: none"> <li>• CG_SOLVER: Conjugate Gradient [default]</li> <li>• CGS_SOLVER: Squared conjugate gradient</li> <li>• BICG_SOLVER: Biconjugate gradient</li> <li>• BICG_STAB_SOLVER: Biconjugate gradient stabilized</li> <li>• GMRES_SOLVER: Generalized Minimal Residual</li> </ul> Default value is CG_SOLVER
in	<i>prec</i>	Option to choose preconditioner in an enumerated variable <ul style="list-style-type: none"> <li>• IDENT_PREC: Identity preconditioner (no preconditioning)</li> <li>• DIAG_PREC: Diagonal preconditioner [default]</li> <li>• SSOR_PREC: SSOR (Symmetric Successive Over Relaxation) preconditioner</li> <li>• DILU_PREC: ILU (Diagonal Incomplete factorization) preconditioner</li> <li>• ILU_PREC: ILU (Incomplete factorization) preconditioner</li> </ul> Default value is DIAG_PREC
in	<i>max_it</i>	Maximum number of allowed iterations. Default value is 1000.
in	<i>toler</i>	Tolerance for convergence. Default value is 1.e-8

**T\_\* get ( ) const**

Return C-Array.

Non zero terms of matrix is stored row by row.

**T\_get ( size\_t i, size\_t j ) const** [virtual]

Return entry (i, j) of matrix if this one is stored, 0 otherwise.

Parameters

in	<i>i</i>	Row index (Starting from 1)
in	<i>j</i>	Column index (Starting from 1)

Implements [Matrix< T\\_\\* >](#).

**TrMatrix ( )**

Default constructor.

Initialize a zero dimension tridiagonal matrix

**void Laplace1D ( real\_t h )**

Define matrix as the one of 3-point finite difference discretization of the second derivative.

Parameters

<code>in</code>	<code>h</code>	mesh size
-----------------	----------------	-----------

**void setSize ( size\_t size )**

Set size (number of rows) of matrix.

Parameters

<code>in</code>	<code>size</code>	Number of rows and columns.
-----------------	-------------------	-----------------------------

**void Axy ( T\_ a, const TrMatrix< T\_ > & m )**

Add to matrix the product of a matrix by a scalar.

Parameters

<code>in</code>	<code>a</code>	Scalar to premultiply
<code>in</code>	<code>m</code>	Matrix by which a is multiplied. The result is added to current instance

**void Axy ( T\_ a, const Matrix< T\_ > \* m ) [virtual]**

Add to matrix the product of a matrix by a scalar.

Parameters

<code>in</code>	<code>a</code>	Scalar to premultiply
<code>in</code>	<code>m</code>	Matrix by which a is multiplied. The result is added to current instance

Implements [Matrix< T\\_ >](#).

**T\_ operator() ( size\_t i, size\_t j ) const [virtual]**

Operator () (Constant version).

Parameters

<code>in</code>	<code>i</code>	Row index
<code>in</code>	<code>j</code>	Column index

Implements [Matrix< T\\_ >](#).

**T\_& operator() ( size\_t i, size\_t j ) [virtual]**

Operator () (Non constant version).

Parameters

<code>in</code>	<code>i</code>	Row index
<code>in</code>	<code>j</code>	Column index

Implements [Matrix< T\\_ >](#).

**TrMatrix< T\_ > & operator= ( const TrMatrix< T\_ > & m )**

Operator =.

Copy matrix m to current matrix instance.

**TrMatrix<T\_>& operator\*= ( const T\_ & x )**

Operator \*.=.

Premultiply matrix entries by constant value x.

**int solve ( Vect< T\_ > & b, bool fact = true )** [virtual]

Solve a linear system with current matrix (forward and back substitution).

Parameters

in,out	<i>b</i>	<a href="#">Vect</a> instance that contains right-hand side on input and solution on output.
in	<i>fact</i>	Unused argument

Returns

- 0 if solution was normally performed,
- n if the n-th pivot is null.

**Warning:** Matrix is modified after this function.

Implements [Matrix< T\\_ >](#).

**int solve ( const Vect< T\_ > & b, Vect< T\_ > & x, bool fact = false )** [virtual]

Solve a linear system with current matrix (forward and back substitution).

Parameters

in	<i>b</i>	<a href="#">Vect</a> instance that contains right-hand side.
out	<i>x</i>	<a href="#">Vect</a> instance that contains solution.
in	<i>fact</i>	Unused argument

Returns

- 0 if solution was normally performed,
- n if the n-th pivot is null.

**Warning:** Matrix is modified after this function.

Implements [Matrix< T\\_ >](#).

**Grid ( real\_t xm, real\_t xM, size\_t npx )**

Construct a 1-D structured grid given its extremal coordinates and number of intervals.

Parameters

in	<i>xm</i>	Minimal value for x
in	<i>xM</i>	Maximal value for x
in	<i>npx</i>	Number of grid intervals in the x-direction

**Grid ( real\_t xm, real\_t xM, real\_t ym, real\_t yM, size\_t npx, size\_t npy )**

Construct a 2-D structured grid given its extremal coordinates and number of intervals.

Parameters

<code>in</code>	<code>xm</code>	Minimal value for x
<code>in</code>	<code>xM</code>	Maximal value for x
<code>in</code>	<code>ym</code>	Minimal value for y
<code>in</code>	<code>yM</code>	Maximal value for y
<code>in</code>	<code>npx</code>	Number of grid intervals in the x-direction
<code>in</code>	<code>npy</code>	Number of grid intervals in the y-direction

**Grid ( Point< real.t > m, Point< real.t > M, size.t npx, size.t npy )**

Construct a 2-D structured grid given its extremal coordinates and number of intervals.

Parameters

<code>in</code>	<code>m</code>	Minimal coordinate value
<code>in</code>	<code>M</code>	Maximal coordinate value
<code>in</code>	<code>npx</code>	Number of grid intervals in the x-direction
<code>in</code>	<code>npy</code>	Number of grid intervals in the y-direction

**Grid ( real.t xm, real.t xM, real.t ym, real.t yM, real.t zm, real.t zM, size.t npx, size.t npy, size.t npz )**

Construct a 3-D structured grid given its extremal coordinates and number of intervals.

Parameters

<code>in</code>	<code>xm</code>	Minimal value for x
<code>in</code>	<code>xM</code>	Maximal value for x
<code>in</code>	<code>ym</code>	Minimal value for y
<code>in</code>	<code>yM</code>	Maximal value for y
<code>in</code>	<code>zm</code>	Minimal value for z
<code>in</code>	<code>zM</code>	Maximal value for z
<code>in</code>	<code>npx</code>	Number of grid intervals in the x-direction
<code>in</code>	<code>npy</code>	Number of grid intervals in the y-direction
<code>in</code>	<code>npz</code>	Number of grid intervals in the z-direction

**Grid ( Point< real.t > m, Point< real.t > M, size.t npx, size.t npy, size.t npz )**

Construct a 3-D structured grid given its extremal coordinates and number of intervals.

Parameters

<code>in</code>	<code>m</code>	Minimal coordinate value
<code>in</code>	<code>M</code>	Maximal coordinate value
<code>in</code>	<code>npx</code>	Number of grid intervals in the x-direction
<code>in</code>	<code>npy</code>	Number of grid intervals in the y-direction
<code>in</code>	<code>npz</code>	Number of grid intervals in the z-direction

**void setXMin ( const Point< real.t > &x )**

Set min. coordinates of the domain.

Parameters

<b>in</b>	<i>x</i>	Minimal values of coordinates
-----------	----------	-------------------------------

**void setXMax ( const Point< real\_t > & x )**

Set max. coordinates of the domain.

Parameters

<b>in</b>	<i>x</i>	Maximal values of coordinates
-----------	----------	-------------------------------

**void setDomain ( real\_t xmin, real\_t xmax )**

Set Dimensions of the domain: 1-D case.

Parameters

<b>in</b>	<i>xmin</i>	Minimal value of x-coordinate
<b>in</b>	<i>xmax</i>	Maximal value of x-coordinate

**void setDomain ( real\_t xmin, real\_t xmax, real\_t ymin, real\_t ymax )**

Set Dimensions of the domain: 2-D case.

Parameters

<b>in</b>	<i>xmin</i>	Minimal value of x-coordinate
<b>in</b>	<i>xmax</i>	Maximal value of x-coordinate
<b>in</b>	<i>ymin</i>	Minimal value of y-coordinate
<b>in</b>	<i>ymax</i>	Maximal value of y-coordinate

**void setDomain ( real\_t xmin, real\_t xmax, real\_t ymin, real\_t ymax, real\_t zmin, real\_t zmax )**

Set Dimensions of the domain: 3-D case.

Parameters

<b>in</b>	<i>xmin</i>	Minimal value of x-coordinate
<b>in</b>	<i>xmax</i>	Maximal value of x-coordinate
<b>in</b>	<i>ymin</i>	Minimal value of y-coordinate
<b>in</b>	<i>ymax</i>	Maximal value of y-coordinate
<b>in</b>	<i>zmin</i>	Minimal value of z-coordinate
<b>in</b>	<i>zmax</i>	Maximal value of z-coordinate

**void setDomain ( Point< real\_t > xmin, Point< real\_t > xmax )**

Set Dimensions of the domain: 3-D case.

Parameters

<b>in</b>	<i>xmin</i>	Minimal coordinate value
<b>in</b>	<i>xmax</i>	Maximal coordinate value

**void setN ( size\_t *nx*, size\_t *ny* = 0, size\_t *nz* = 0 )**

Set number of grid intervals in the x, y and z-directions.

Number of points is the number of intervals plus one in each direction

## Parameters

<code>in</code>	<code>nx</code>	Number of grid intervals in the x-direction
<code>in</code>	<code>ny</code>	Number of grid intervals in the y-direction (Default=0: 1-D grid)
<code>in</code>	<code>nz</code>	Number of grid intervals in the z-direction (Default=0: 1-D or 2-D grid)

## Remarks

: The size of the grid (`xmin` and `xmax`) must have been defined before.

**size\_t getNy ( ) const**

Return number of grid intervals in the y-direction.

`ny=0` for 1-D domains (segments)

**size\_t getNz ( ) const**

Return number of grid intervals in the z-direction.

`nz=0` for 1-D (segments) and 2-D domains (rectangles)

**void setCode ( string exp, int code )**

Set a code for some grid points.

## Parameters

<code>in</code>	<code>exp</code>	Regular expression that determines the set of grid points on which the code is applied.
<code>in</code>	<code>code</code>	Code to assign.

**void setCode ( int side, int code )**

Set a code for grid points on sides.

## Parameters

<code>in</code>	<code>side</code>	<a href="#">Side</a> for which code is assigned. Possible values are: <code>MIN_X</code> , <code>MAX_X</code> , <code>MIN_Y</code> , <code>MAX_Y</code> , <code>MIN_Z</code> , <code>MAX_Z</code>
<code>in</code>	<code>code</code>	Code to assign.

**int getCode ( int side ) const**

Return code for a side number.

## Parameters

<code>in</code>	<code>side</code>	<a href="#">Side</a> for which code is returned. Possible values are: <code>MIN_X</code> , <code>MAX_X</code> , <code>MIN_Y</code> , <code>MAX_Y</code> , <code>MIN_Z</code> , <code>MAX_Z</code>
-----------------	-------------------	---

**int getCode ( size\_t i, size\_t j ) const**

Return code for a grid point.

Parameters

<code>in</code>	<code>i</code>	i-th index for node for which code is to be returned.
<code>in</code>	<code>j</code>	j-th index for node for which code is to be returned.

**int getCode ( size\_t *i*, size\_t *j*, size\_t *k* ) const**

Return code for a grid point.

Parameters

<code>in</code>	<code>i</code>	i-th index for node for which code is to be returned.
<code>in</code>	<code>j</code>	j-th index for node for which code is to be returned.
<code>in</code>	<code>k</code>	k-th index for node for which code is to be returned.

**void Deactivate ( size\_t *i* )**

Change state of a cell from active to inactive (1-D grid)

Parameters

<code>in</code>	<code>i</code>	grid cell to remove
-----------------	----------------	---------------------

**void Deactivate ( size\_t *i*, size\_t *j* )**

Change state of a cell from active to inactive (2-D grid)

Parameters

<code>in</code>	<code>i</code>	i-th index for grid cell to remove. If this value is 0, all cells (*,j) are deactivated
<code>in</code>	<code>j</code>	j-th index for grid cell to remove If this value is 0, all cells (i,*) are deactivated

Remarks

if i and j have value 0 all grid cells are deactivated !!

**void Deactivate ( size\_t *i*, size\_t *j*, size\_t *k* )**

Change state of a cell from active to inactive (2-D grid)

Parameters

<code>in</code>	<code>i</code>	i-th index for grid cell to remove. If this value is 0, all cells (*,j,k) are deactivated
<code>in</code>	<code>j</code>	j-th index for grid cell to remove If this value is 0, all cells (i,*,k) are deactivated
<code>in</code>	<code>k</code>	k-th index for grid cell to remove If this value is 0, all cells (i,j,*) are deactivated

**int isActive ( size\_t *i* ) const**

Say if cell is active or not (1-D grid)

Parameters

<code>in</code>	<code>i</code>	Index of cell
-----------------	----------------	---------------

Returns

1 if cell is active, 0 if not

**int isActive ( size\_t *i*, size\_t *j* ) const**

Say if cell is active or not (2-D grid)

Parameters

<code>in</code>	<code>i</code>	i-th index of cell
<code>in</code>	<code>j</code>	j-th index of cell

Returns

1 if cell is active, 0 if not

**int isActive ( size\_t *i*, size\_t *j*, size\_t *k* ) const**

Say if cell is active or not (3-D grid)

Parameters

<code>in</code>	<code>i</code>	i-th index of cell
<code>in</code>	<code>j</code>	j-th index of cell
<code>in</code>	<code>k</code>	k-th index of cell

Returns

1 if cell is active, 0 if not

**Iter ( )**

Default Constructor.

This constructor set default values: the maximal number of iterations is set to 100 and the tolerance to  $1.e-8$

**Iter ( int *max\_it*, real\_t *toler* )**

Constructor with iteration parameters.

Parameters

<code>in</code>	<code>max_it</code>	Maximum number of iterations
<code>in</code>	<code>toler</code>	Tolerance value for convergence

**bool check ( Vect< T\_ > & *u*, const Vect< T\_ > & *v*, int *opt* = 2 )**

Check convergence.

## Parameters

<code>in,out</code>	$u$	Solution vector at previous iteration
<code>in</code>	$v$	Solution vector at current iteration
<code>in</code>	$opt$	Vector norm for convergence checking 1: 1-norm, 2: 2-norm, 0: Max. norm [Default: 2]

## Returns

true if convergence criterion is satisfied, false if not

After checking, this function copied  $v$  into  $u$ .

**bool check ( T\_ &  $u$ , const T\_ &  $v$  )**

Check convergence for a scalar case (one equation)

## Parameters

<code>in,out</code>	$u$	Solution at previous iteration
<code>in</code>	$v$	Solution at current iteration

## Returns

true if convergence criterion is satisfied, false if not

After checking, this function copied  $v$  into  $u$ .

# Chapter 6

## Namespace Documentation

### 6.1 OFELI Namespace Reference

A namespace to group all library classes, functions, ...

#### Classes

- class [Bar2DL2](#)  
*To build element equations for Planar Elastic Bar element with 2 DOF (Degrees of Freedom) per node.*
- class [Beam3DL2](#)  
*To build element equations for 3-D beam equations using 2-node lines.*
- class [BiotSavart](#)  
*Class to compute the magnetic induction from the current density using the Biot-Savart formula.*
- class [BMatrix](#)  
*To handle band matrices.*
- class [Brick](#)  
*To store and treat a brick (parallelepiped) figure.*
- class [Circle](#)  
*To store and treat a circular figure.*
- class [DC1DL2](#)  
*Builds finite element arrays for thermal diffusion and convection in 1-D using 2-Node elements.*
- class [DC2DT3](#)  
*Builds finite element arrays for thermal diffusion and convection in 2-D domains using 3-Node triangles.*
- class [DC2DT6](#)  
*Builds finite element arrays for thermal diffusion and convection in 2-D domains using 6-Node triangles.*
- class [DC3DAT3](#)  
*Builds finite element arrays for thermal diffusion and convection in 3-D domains with axisymmetry using 3-Node triangles.*
- class [DC3DT4](#)  
*Builds finite element arrays for thermal diffusion and convection in 3-D domains using 4-Node tetrahedra.*
- class [DG](#)  
*Enables preliminary operations and utilities for the Discontinuous Galerkin method.*
- class [DMatrix](#)  
*To handle dense matrices.*
- class [Domain](#)

- To store and treat finite element geometric information.*

  - class [DSMatrix](#)
- To handle symmetric dense matrices.*

  - class [EC2D1T3](#)
- Eddy current problems in 2-D domains using solenoidal approximation.*

  - class [EC2D2T3](#)
- Eddy current problems in 2-D domains using transversal approximation.*

  - class [Edge](#)
- To describe an edge.*

  - class [EdgeList](#)
- Class to construct a list of edges having some common properties.*

  - class [EigenProblemSolver](#)
- Class to find eigenvalues and corresponding eigenvectors of a given matrix in a generalized eigenproblem, i.e. Find scalars  $l$  and non-null vectors  $v$  such that  $[K]\{v\} = l[M]\{v\}$  where  $[K]$  and  $[M]$  are symmetric matrices. The eigenproblem can be originated from a PDE. For this, we will refer to the matrices  $K$  and  $M$  as Stiffness and Mass matrices respectively.*

  - class [Elas2DQ4](#)
- To build element equations for 2-D linearized elasticity using 4-node quadrilaterals.*

  - class [Elas2DT3](#)
- To build element equations for 2-D linearized elasticity using 3-node triangles.*

  - class [Elas3DH8](#)
- To build element equations for 3-D linearized elasticity using 8-node hexahedra.*

  - class [Elas3DT4](#)
- To build element equations for 3-D linearized elasticity using 4-node tetrahedra.*

  - class [Element](#)
- To store and treat finite element geometric information.*

  - class [ElementList](#)
- Class to construct a list of elements having some common properties.*

  - class [Ellipse](#)
- To store and treat an ellipsoidal figure.*

  - class [Equa](#)
- Mother abstract class to describe equation.*

  - class [Equa\\_Electromagnetics](#)
- Abstract class for Electromagnetics [Equation](#) classes.*

  - class [Equa\\_Fluid](#)
- Abstract class for Fluid Dynamics [Equation](#) classes.*

  - class [Equa\\_Laplace](#)
- Abstract class for classes about the Laplace equation.*

  - class [Equa\\_Porous](#)
- Abstract class for Porous Media Finite Element classes.*

  - class [Equa\\_Solid](#)
- Abstract class for Solid Mechanics Finite Element classes.*

  - class [Equa\\_Therm](#)
- Abstract class for Heat transfer Finite Element classes.*

  - class [Equation](#)
- Abstract class for all equation classes.*

  - class [Estimator](#)

- To calculate an a posteriori estimator of the solution.*

  - class [FastMarching](#)  
*class for the fast marching algorithm on uniform grids*
  - class [FastMarching1DG](#)  
*class for the fast marching algorithm on 1-D uniform grids*
  - class [FastMarching2DG](#)  
*class for the fast marching algorithm on 2-D uniform grids*
  - class [FastMarching3DG](#)  
*class for the fast marching algorithm on 3-D uniform grids*
  - class [FEShape](#)  
*Parent class from which inherit all finite element shape classes.*
  - class [Figure](#)  
*To store and treat a figure (or shape) information.*
  - class [Funct](#)  
*A simple class to parse real valued functions.*
  - class [Gauss](#)  
*Calculate data for Gauss integration.*
  - class [Grid](#)  
*To manipulate structured grids.*
  - class [HelmholtzBT3](#)  
*Builds finite element arrays for Helmholtz equations in a bounded media using 3-Node triangles.*
  - class [Hexa8](#)  
*Defines a three-dimensional 8-node hexahedral finite element using Q1-isoparametric interpolation.*
  - class [ICPG1D](#)  
*Class to solve the Inviscid compressible fluid flows (Euler equations) for perfect gas in 1-D.*
  - class [ICPG2DT](#)  
*Class to solve the Inviscid compressible fluid flows (Euler equations) for perfect gas in 2-D.*
  - class [ICPG3DT](#)  
*Class to solve the Inviscid compressible fluid flows (Euler equations) for perfect gas in 3-D.*
  - class [Integration](#)  
*Class for numerical integration methods.*
  - class [IOField](#)  
*Enables working with files in the XML Format.*
  - class [IPF](#)  
*To read project parameters from a file in [IPF](#) format.*
  - class [Iter](#)  
*Class to drive an iterative process.*
  - class [Laplace1DL2](#)  
*To build element equation for a 1-D elliptic equation using the 2-Node line element ( $P_1$ ).*
  - class [Laplace1DL3](#)  
*To build element equation for the 1-D elliptic equation using the 3-Node line ( $P_2$ ).*
  - class [Laplace2DT3](#)  
*To build element equation for the Laplace equation using the 2-D triangle element ( $P_1$ ).*
  - class [Laplace2DT6](#)  
*To build element equation for the Laplace equation using the 2-D triangle element ( $P_2$ ).*
  - class [LaplaceDG2DP1](#)

- To build and solve the linear system for the Poisson problem using the [DG](#)  $P_1$  2-D triangle element.

  - class [LCL1D](#)
- Class to solve the linear conservation law (Hyperbolic equation) in 1-D by a MUSCL Finite Volume scheme.

  - class [LCL2DT](#)
- Class to solve the linear hyperbolic equation in 2-D by a MUSCL Finite Volume scheme on triangles.

  - class [LCL3DT](#)
- Class to solve the linear conservation law equation in 3-D by a MUSCL Finite Volume scheme on tetrahedra.

  - class [Line2](#)
- To describe a 2-Node planar line finite element.

  - class [Line3](#)
- To describe a 3-Node quadratic planar line finite element.

  - class [LinearSolver](#)
- Class to solve systems of linear equations by iterative methods.

  - class [LocalMatrix](#)
- Handles small size matrices like element matrices, with a priori known size.

  - class [LocalVect](#)
- Handles small size vectors like element vectors.

  - class [LPSolver](#)
- To solve a linear programming problem.

  - class [Material](#)
- To treat material data. This class enables reading material data in material data files. It also returns these informations by means of its members.

  - class [Matrix](#)
- Virtual class to handle matrices for all storage formats.

  - class [Mesh](#)
- To store and manipulate finite element meshes.

  - class [MeshAdapt](#)
- To adapt mesh in function of given solution.

  - class [Muscl](#)
- Parent class for hyperbolic solvers with Muscl scheme.

  - class [Muscl1D](#)
- Class for 1-D hyperbolic solvers with [Muscl](#) scheme.

  - class [Muscl2DT](#)
- Class for 2-D hyperbolic solvers with [Muscl](#) scheme.

  - class [Muscl3DT](#)
- Class for 3-D hyperbolic solvers with [Muscl](#) scheme using tetrahedra.

  - class [MyNLAS](#)
- Abstract class to define by user specified function.

  - class [MyOpt](#)
- Abstract class to define by user specified optimization function.

  - class [NLASSolver](#)
- To solve a system of nonlinear algebraic equations of the form  $f(u) = 0$ .

  - class [Node](#)
- To describe a node.

  - class [NodeList](#)
- Class to construct a list of nodes having some common properties.

  - class [NSP2DQ41](#)

*Builds finite element arrays for incompressible Navier-Stokes equations in 2-D domains using  $Q_1/P_0$  element and a penalty formulation for the incompressibility condition.*

- class [ODESolver](#)  
*To solve a system of ordinary differential equations.*
- class [OFELIException](#)  
*To handle exceptions in [OFELI](#).*
- class [OptSolver](#)  
*To solve an optimization problem with bound constraints.*
- class [Partition](#)  
*To partition a finite element mesh into balanced submeshes.*
- class [Penta6](#)  
*Defines a 6-node pentahedral finite element using  $P_1$  interpolation in local coordinates  $(s.x, s.y)$  and  $Q_1$  isoparametric interpolation in local coordinates  $(s.x, s.z)$  and  $(s.y, s.z)$ .*
- class [PhaseChange](#)  
*This class enables defining phase change laws for a given material.*
- class [Point](#)  
*Defines a point with arbitrary type coordinates.*
- class [Point2D](#)  
*Defines a 2-D point with arbitrary type coordinates.*
- class [Polygon](#)  
*To store and treat a polygonal figure.*
- class [Prec](#)  
*To set a preconditioner.*
- class [Prescription](#)  
*To prescribe various types of data by an algebraic expression. Data may consist in boundary conditions, forces, tractions, fluxes, initial condition. All these data types can be defined through an enumerated variable.*
- class [Quad4](#)  
*Defines a 4-node quadrilateral finite element using  $Q_1$  isoparametric interpolation.*
- class [Reconstruction](#)  
*To perform various reconstruction operations.*
- class [Rectangle](#)  
*To store and treat a rectangular figure.*
- class [Side](#)  
*To store and treat finite element sides (edges in 2-D or faces in 3-D)*
- class [SideList](#)  
*Class to construct a list of sides having some common properties.*
- class [SkMatrix](#)  
*To handle square matrices in skyline storage format.*
- class [SkSMatrix](#)  
*To handle symmetric matrices in skyline storage format.*
- class [Sphere](#)  
*To store and treat a sphere.*
- class [SpMatrix](#)  
*To handle matrices in sparse storage format.*
- class [SteklovPoincare2DBE](#)  
*Solver of the Steklov Poincare problem in 2-D geometries using piecewise constant boundary elemen.*

- class [Tabulation](#)

*To read and manipulate tabulated functions.*

- class [Tetra4](#)

*Defines a three-dimensional 4-node tetrahedral finite element using  $P_1$  interpolation.*

- class [Timer](#)

*To handle elapsed time counting.*

- class [TimeStepping](#)

*To solve time stepping problems, i.e. systems of linear ordinary differential equations of the form  $[A2]\{y''\} + [A1]\{y'\} + [A0]\{y\} = \{b\}$ .*

- class [TINS2DT3S](#)

*Builds finite element arrays for transient incompressible fluid flow using Navier-Stokes equations in 2-D domains. Numerical approximation uses stabilized 3-node triangle finite elements for velocity and pressure. 2nd-order projection scheme is used for time integration.*

- class [TINS3DT4S](#)

*Builds finite element arrays for transient incompressible fluid flow using Navier-Stokes equations in 3- $\leftrightarrow$  D domains. Numerical approximation uses stabilized 4-node tetrahedral finite elements for velocity and pressure. 2nd-order projection scheme is used for time integration.*

- class [Triang3](#)

*Defines a 3-Node ( $P_1$ ) triangle.*

- class [Triang6S](#)

*Defines a 6-Node straight triangular finite element using  $P_2$  interpolation.*

- class [Triangle](#)

*To store and treat a triangle.*

- class [triangle](#)

*Defines a triangle. The reference element is the rectangle triangle with two unit edges.*

- class [TrMatrix](#)

*To handle tridiagonal matrices.*

- class [Vect](#)

*To handle general purpose vectors.*

- class [WaterPorous2D](#)

*To solve water flow equations in porous media (1-D)*

## Enumerations

- `enum PDE_Terms {`

## Functions

- `ostream & operator<<` (`ostream &s`, `const Muscl3DT &m`)  
*Output mesh data as calculated in class `Muscl3DT`.*
- `T_ * A ()`  
*Return element matrix.*

- `T_ * b ()`  
*Return element right-hand side.*
- `T_ * Prev ()`  
*Return element previous vector.*
- `ostream & operator<< (ostream &s, const complex.t &x)`  
*Output a complex number.*
- `ostream & operator<< (ostream &s, const std::string &c)`  
*Output a string.*
- `template<class T_ >`  
`ostream & operator<< (ostream &s, const vector< T_ > &v)`  
*Output a vector instance.*
- `template<class T_ >`  
`ostream & operator<< (ostream &s, const std::list< T_ > &l)`  
*Output a vector instance.*
- `template<class T_ >`  
`ostream & operator<< (ostream &s, const std::pair< T_, T_ > &a)`  
*Output a pair instance.*
- `void saveField (Vect< real.t > &v, string output_file, int opt)`  
*Save a vector to an output file in a given file format.*
- `void saveField (const Vect< real.t > &v, const Mesh &mesh, string output_file, int opt)`  
*Save a vector to an output file in a given file format.*
- `void saveField (Vect< real.t > &v, const Grid &g, string output_file, int opt)`  
*Save a vector to an output file in a given file format, for a structured grid data.*
- `void saveGnuplot (string input_file, string output_file, string mesh_file, int f=1)`  
*Save a vector to an input **Gnuplot** file.*
- `void saveGnuplot (Mesh &mesh, string input_file, string output_file, int f=1)`  
*Save a vector to an input **Gnuplot** file.*
- `void saveTecplot (string input_file, string output_file, string mesh_file, int f=1)`  
*Save a vector to an output file to an input **Tecplot** file.*
- `void saveTecplot (Mesh &mesh, string input_file, string output_file, int f=1)`  
*Save a vector to an output file to an input **Tecplot** file.*
- `void saveVTK (string input_file, string output_file, string mesh_file, int f=1)`  
*Save a vector to an output **VTK** file.*
- `void saveVTK (Mesh &mesh, string input_file, string output_file, int f=1)`  
*Save a vector to an output **VTK** file.*
- `void saveGmsh (string input_file, string output_file, string mesh_file, int f=1)`  
*Save a vector to an output **Gmsh** file.*
- `void saveGmsh (Mesh &mesh, string input_file, string output_file, int f=1)`  
*Save a vector to an output **Gmsh** file.*
- `ostream & operator<< (ostream &s, const Tabulation &t)`  
*Output Tabulated function data.*
- `template<class T_ , size_t N_ , class E_ >`  
`void element.assembly (const E_ &e, const LocalVect< T_ , N_ > &be, Vect< T_ > &b)`  
*Assemble local vector into global vector.*
- `template<class T_ , size_t N_ , class E_ >`  
`void element.assembly (const E_ &e, const LocalMatrix< T_ , N_ , N_ > &ae, Vect< T_ > &b)`  
*Assemble diagonal local vector into global vector.*

- `template<class T_, size_t N_, class E_>`  
`void element_assembly (const E_ &e, const LocalMatrix< T_, N_, N_ > &ae, Matrix< T_ > *A)`  
*Assemble local matrix into global matrix.*
- `template<class T_, size_t N_, class E_>`  
`void element_assembly (const E_ &e, const LocalMatrix< T_, N_, N_ > &ae, SkMatrix< T_ > &A)`  
*Assemble local matrix into global skyline matrix.*
- `template<class T_, size_t N_, class E_>`  
`void element_assembly (const E_ &e, const LocalMatrix< T_, N_, N_ > &ae, SkSMatrix< T_ > &A)`  
*Assemble local matrix into global symmetric skyline matrix.*
- `template<class T_, size_t N_, class E_>`  
`void element_assembly (const E_ &e, const LocalMatrix< T_, N_, N_ > &ae, SpMatrix< T_ > &A)`  
*Assemble local matrix into global sparse matrix.*
- `template<class T_, size_t N_>`  
`void side_assembly (const Element &e, const LocalMatrix< T_, N_, N_ > &ae, SpMatrix< T_ > &A)`  
*Side assembly of local matrix into global matrix (as instance of class SpMatrix).*
- `template<class T_, size_t N_>`

## Additional Inherited Members

### 7.1.1 Detailed Description

To build element equations for Planar Elastic Bar element with 2 DOF (Degrees of Freedom) per node.

This class implements a planar (two-dimensional) elastic bar using 2-node lines. Note that members calculating element arrays have as an argument a real `coef` that is multiplied by the contribution of the current element. This makes possible testing different algorithms.

### 7.1.2 Constructor & Destructor Documentation

#### **Bar2DL2 ( )**

Default Constructor.

Constructs an empty equation.

#### **Bar2DL2 ( Mesh & *ms* )**

Constructor using a [Mesh](#) instance.

Parameters

<code>in</code>	<code>ms</code>	Reference <a href="#">Mesh</a> instance
-----------------	-----------------	---

#### **Bar2DL2 ( Mesh & *ms*, Vect< real.t > & *u* )**

Constructor using a [Mesh](#) instance and a solution vector instance.

Parameters

<code>in</code>	<code>ms</code>	Reference <a href="#">Mesh</a> instance
<code>in, out</code>	<code>u</code>	Reference to solution vector

### 7.1.3 Member Function Documentation

#### **void LMass ( real.t *coef* = 1 ) [virtual]**

Add lumped mass matrix to element matrix after multiplying it by coefficient `coef`

Parameters

<code>in</code>	<code>coef</code>	Coefficient to multiply by added term [Default: 1].
-----------------	-------------------	---

Reimplemented from [Equa.Solid< 2, 4, 1, 2 >](#).

#### **void Mass ( real.t *coef* = 1 ) [virtual]**

Add consistent mass matrix to element matrix after multiplying it by coefficient `coef`

Parameters

<code>in</code>	<code>coef</code>	Coefficient to multiply by added term [Default: 1].
-----------------	-------------------	---

Reimplemented from [Equa.Solid< 2, 4, 1, 2 >](#).

#### **void Stiffness ( real.t *coef* = 1. ) [virtual]**

Add element stiffness to left hand side.

Parameters

<code>in</code>	<code>coef</code>	Coefficient to multiply by added term [Default: 1].
-----------------	-------------------	---

Reimplemented from [Equa\\_Solid< 2, 4, 1, 2 >](#).

**void getStresses ( Vect< real.t > & s )**

Return stresses in the truss structure (elementwise)

Parameters

<code>in</code>	<code>s</code>	<a href="#">Vect</a> instance containing axial stresses in elements
-----------------	----------------	---

**void build ( )**

Build the linear system of equations.

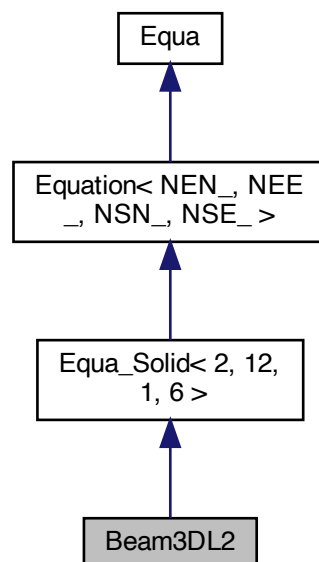

Before using this function, one must have properly selected appropriate options for:

- The choice of a steady state or transient analysis
- In the case of transient analysis, the choice of a time integration scheme and a lumped or consistent mass matrix
- The choice of desired linear system solver

## 7.2 Beam3DL2 Class Reference

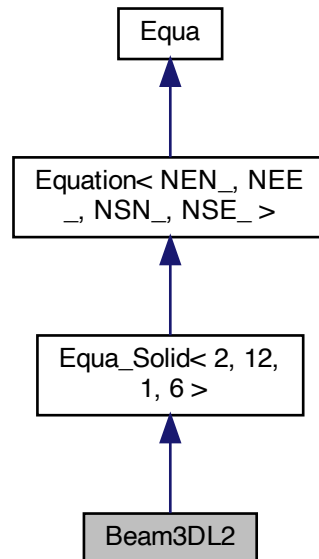

To build element equations for 3-D beam equations using 2-node lines.

## Additional Inherited Members

### 7.2.1 Detailed Description

To build element equations for 3-D beam equations using 2-node lines.

This class enables building finite element arrays for 3-D beam elements using 6 degrees of freedom per node and 2-Node line elements.

### 7.2.2 Constructor & Destructor Documentation

**Beam3DL2** ( Mesh & ms, real.t A, real.t I1, real.t I2 )

Constructor using mesh and constant beam properties.

Parameters

in	<i>ms</i>	<a href="#">Mesh</a> instance
in	<i>A</i>	Section area of the beam
in	<i>I1</i>	first (x) momentum of inertia
in	<i>I2</i>	second (y) momentum of inertia

### Beam3DL2 ( [Mesh](#) & *ms* )

Constructor using a [Mesh](#) instance.

Parameters

in	<i>ms</i>	Reference to <a href="#">Mesh</a> instance
----	-----------	--

### Beam3DL2 ( [Mesh](#) & *ms*, Vect< real.t > & *u* )

Constructor using a [Mesh](#) instance and solution vector.

Parameters

in	<i>ms</i>	Reference to <a href="#">Mesh</a> instance
in,out	<i>u</i>	Solution vector

## 7.2.3 Member Function Documentation

### void set ( real.t *A*, real.t *I1*, real.t *I2* )

Set constant beam properties.

Parameters

in	<i>A</i>	Section area of the beam
in	<i>I1</i>	first (x) momentum of inertia
in	<i>I2</i>	second (y) momentum of inertia

### void set ( const Vect< real.t > & *A*, const Vect< real.t > & *I1*, const Vect< real.t > & *I2* )

Set nonconstant beam properties.

Parameters

in	<i>A</i>	Vector containing section areas of the beam (for each element)
in	<i>I1</i>	Vector containing first (x) momentum of inertia (for each element)
in	<i>I2</i>	Vector containing second (y) momentum of inertia (for each element)

### void getDisp ( Vect< real.t > & *d* )

Get vector of displacements at nodes.

Parameters

out	<i>d</i>	Vector containing three components for each node that are x, y and z displacements.
-----	----------	---

**void AxialForce ( Vect< real\_t > &*f* )**

Return axial force in element.

Parameters

out	$f$	Vector containing axial force in each element. This vector is resized in the function
-----	-----	---

**void ShearForce ( Vect< real.t > & sh )**

Return shear force in element.

Parameters

out	$sh$	Vector containing shear forces (2 components) in each element. This vector is resized in the function
-----	------	---

**void BendingMoment ( Vect< real.t > & m )**

Return bending moment in element.

Parameters

out	$m$	Vector containing bending moments (2 components) in each element. This vector is resized in the function
-----	-----	--

**void TwistingMoment ( Vect< real.t > & m )**

Return twisting moments.

Parameters

out	$m$	Vector containing twisting moment in each element. This vector is resized in the function
-----	-----	---

**void buildEigen ( SkSMatrix< real.t > & K, Vect< real.t > & M )**

Build global stiffness and mass matrices for the eigen system.

Case where the mass matrix is lumped

Parameters

in	$K$	Stiffness matrix
in	$M$	Vector containing diagonal mass matrix

## 7.3 BiotSavart Class Reference

Class to compute the magnetic induction from the current density using the Biot-Savart formula.

### Public Member Functions

- [BiotSavart \(\)](#)

*Compute the complex magnetic induction at a given point using the surface Biot-Savart formula.*
- `Point< complex_t > getBC1 (Point< real_t > x)`

*Compute the complex magnetic induction at a given point using the line Biot-Savart formula.*
- `int run ()`

*Run the calculation by the Biot-Savart formula.*

### 7.3.1 Detailed Description

Class to compute the magnetic induction from the current density using the Biot-Savart formula.

Given a current density vector given at elements, a collection of sides of edges (piecewise constant), this class enables computing the magnetic induction vector (continuous and piecewise linear) using the Ampere equation. This magnetic induction is obtained by using the Biot-Savart formula which can be either a volume, surface or line formula depending on the nature of the current density vector.

Author

Rachid Touzani

Copyright

### 7.3.2 Constructor & Destructor Documentation

**BiotSavart ( Mesh & *ms* )**

Constructor using mesh data.

Parameters

<code>in</code>	<code>ms</code>	<a href="#">Mesh</a> instance
-----------------	-----------------	-------------------------------

**BiotSavart ( Mesh & *ms*, const Vect< real.t > & *J*, Vect< real.t > & *B*, int *code* = 0 )**

Constructor using mesh and vector of real current density.

The current density is assumed piecewise constant

Parameters

<code>in</code>	<code>ms</code>	<a href="#">Mesh</a> instance
<code>in</code>	<code>J</code>	Sidewise vector of current density ( <i>J</i> is a real valued vector), in the case of a surface supported current
<code>in</code>	<code>B</code>	Nodewise vector that contains, once the member function run is used, the magnetic induction
<code>in</code>	<code>code</code>	Only sides with given <i>code</i> support current [Default: 0]

**BiotSavart ( Mesh & *ms*, const Vect< complex.t > & *J*, Vect< complex.t > & *B*, int *code* = 0 )**

Constructor using mesh and vector of complex current density.

The current density is assumed piecewise constant

Parameters

<code>in</code>	<code>ms</code>	<a href="#">Mesh</a> instance
<code>in</code>	<code>J</code>	Sidewise vector of current density ( <i>J</i> is a complex valued vector), in the case of a surface supported current
<code>in</code>	<code>B</code>	Nodewise vector that contains, once the member function run is used, the magnetic induction
<code>in</code>	<code>code</code>	Only sides with given <i>code</i> support current [Default: 0]

### 7.3.3 Member Function Documentation

**void setCurrentDensity ( const Vect< real.t > & *J* )**

Set (real) current density given at elements.

The current density is assumed piecewise constant and real valued. This function can be used in the case of the volume Biot-Savart formula.

Parameters

<code>in</code>	<code>J</code>	Current density vector ( <a href="#">Vect</a> instance) and real entries
-----------------	----------------	--

**void setCurrentDensity ( const Vect< complex.t > & *J* )**

Set (real) current density given at elements.

The current density is assumed piecewise constant and complex valued. This function can be used in the case of the volume Biot-Savart formula.

Parameters

<code>in</code>	<code>J</code>	Current density vector ( <a href="#">Vect</a> instance) of complex entries
-----------------	----------------	--

**void setMagneticInduction ( Vect< real.t > & *B* )**

Transmit (real) magnetic induction vector given at nodes.

Parameters

out	$B$	Magnetic induction vector ( <a href="#">Vect</a> instance) and real entries
-----	-----	---

**void setMagneticInduction ( Vect< complex.t > & B )**

Transmit (complex) magnetic induction vector given at nodes.

Parameters

out	$B$	Magnetic induction vector ( <a href="#">Vect</a> instance) and complex entries
-----	-----	--

**void setPermeability ( real.t  $\mu$  )**

Set the magnetic permeability coefficient.

Parameters

in	$\mu$	Magnetic permeability
----	-------	-----------------------

**void setBoundary ( )**

Choose to compute the magnetic induction at boundary nodes only.

By default the magnetic induction is computed (using the function `run`) at all mesh nodes

Note

This function has no effect for surface of line Biot-Savart formula

**Point<real.t> getB3 ( Point< real.t >  $x$  )**

Compute the real magnetic induction at a given point using the volume Biot-Savart formula.

This function computes a real valued magnetic induction for a real valued current density field

Parameters

in	$x$	Coordinates of point at which the magnetic induction is computed
----	-----	--

Returns

Value of the magnetic induction at  $x$

**Point<real.t> getB2 ( Point< real.t >  $x$  )**

Compute the real magnetic induction at a given point using the surface Biot-Savart formula.

This function computes a real valued magnetic induction for a real valued current density field

Parameters

in	$x$	Coordinates of point at which the magnetic induction is computed
----	-----	--

Returns

Value of the magnetic induction at  $x$

**Point<real\_t> getB1 ( Point< real\_t > x )**

Compute the real magnetic induction at a given point using the line Biot-Savart formula.

This function computes a real valued magnetic induction for a real valued current density field

Parameters

in	$x$	Coordinates of point at which the magnetic induction is computed
----	-----	--

Returns

Value of the magnetic induction at  $x$

**Point<complex\_t> getBC3 ( Point< real\_t > x )**

Compute the complex magnetic induction at a given point using the volume Biot-Savart formula.

This function computes a complex valued magnetic induction for a complex valued current density field

Parameters

in	$x$	Coordinates of point at which the magnetic induction is computed
----	-----	--

Returns

Value of the magnetic induction at  $x$

**Point<complex\_t> getBC2 ( Point< real\_t > x )**

Compute the complex magnetic induction at a given point using the surface Biot-Savart formula.

This function computes a complex valued magnetic induction for a complex valued current density field

Parameters

in	$x$	Coordinates of point at which the magnetic induction is computed
----	-----	--

Returns

Value of the magnetic induction at  $x$

**Point<complex\_t> getBC1 ( Point< real\_t > x )**

Compute the complex magnetic induction at a given point using the line Biot-Savart formula.

This function computes a complex valued magnetic induction for a complex valued current density field

Parameters

in	$x$	Coordinates of point at which the magnetic induction is computed
----	-----	--

Returns

Value of the magnetic induction at  $x$

```
int run ( )
```

Run the calculation by the Biot-Savart formula.

This function computes the magnetic induction, which is stored in the vector B given in the constructor

### 7.4.1 Detailed Description

**template<class T\_>class OFELI::BMatrix< T\_ >**

To handle band matrices.

This class enables storing and manipulating band matrices. The matrix can have different numbers of lower and upper co-diagonals

## Template Parameters

<i>T_</i>	Data type (double, float, complex<double>, ...)
-----------	---

## Author

Rachid Touzani

## Copyright

GNU Lesser Public License

**7.4.2 Constructor & Destructor Documentation****BMatrix ( )**

Default constructor.

Initialize a zero dimension band matrix

**BMatrix ( size\_t size, int ld, int ud )**

Constructor that for a band matrix with given size and bandwidth.

Assign 0 to all matrix entries.

Parameters

in	<i>size</i>	Number of rows and columns
in	<i>ld</i>	Number of lower co-diagonals (must be > 0)
in	<i>ud</i>	Number of upper co-diagonals (must be > 0)

**7.4.3 Member Function Documentation****void setSize ( size\_t size, int ld, int ud )**

Set size (number of rows) and storage of matrix.

Parameters

in	<i>size</i>	Number of rows and columns
in	<i>ld</i>	Number of lower co-diagonals (must be > 0)
in	<i>ud</i>	Number of upper co-diagonals (must be > 0)

**void Axy ( T\_ a, const BMatrix< T\_ > & x )**

Add to matrix the product of a matrix by a scalar.

Parameters

in	<i>a</i>	Scalar to premultiply
in	<i>x</i>	Matrix by which a is multiplied. The result is added to current instance

**void Axy ( T\_ a, const Matrix< T\_ > \* x ) [virtual]**

Add to matrix the product of a matrix by a scalar.

Parameters

in	$a$	Scalar to premultiply
in	$x$	Matrix by which $a$ is multiplied. The result is added to current instance

Implements [Matrix< T\\_ >](#).

**T\_ operator() ( size\_t i, size\_t j ) const** [virtual]

Operator () (Constant version).

Parameters

in	$i$	Row index
in	$j$	Column index

Implements [Matrix< T\\_ >](#).

**T\_& operator() ( size\_t i, size\_t j )** [virtual]

Operator () (Non constant version).

Parameters

in	$i$	Row index
in	$j$	Column index

Implements [Matrix< T\\_ >](#).

**BMatrix<T\_>& operator= ( const BMatrix< T\_ > & m )**

Operator =.

Copy matrix  $m$  to current matrix instance.

**BMatrix<T\_>& operator\*= ( const T\_ & x )**

Operator \*.

Premultiply matrix entries by constant value  $x$

**BMatrix<T\_>& operator+= ( const T\_ & x )**

Operator +.

Add constant  $x$  to matrix entries.

**int setLU ( )**

Factorize the matrix (LU factorization)

LU factorization of the matrix is realized. Note that since this is an in place factorization, the contents of the matrix are modified.

Returns

- 0 if factorization was normally performed,
- $n$  if the  $n$ -th pivot is null.

Remarks

A flag in this class indicates after factorization that this one has been realized, so that, if the member function solve is called after this no further factorization is done.

```
int solve ( Vect< T_ > & b, bool fact = false ) [virtual]
```

Solve linear system.

The linear system having the current instance as a matrix is solved by using the LU decomposition. Solution is thus realized after a factorization step and a forward/backward substitution step. The factorization step is realized only if this was not already done.

Note that this function modifies the matrix contents if a factorization is performed. Naturally, if the matrix has been modified after using this function, the user has to refactorize it using the function `setLU`. This is because the class has no non-expensive way to detect if the matrix has been modified. The function `setLU` realizes the factorization step only.

Parameters

in,out	<i>b</i>	<a href="#">Vect</a> instance that contains right-hand side on input and solution on output.
in	<i>fact</i>	Unused argument

Returns

- 0 if solution was normally performed,
- *n* if the *n*-th pivot is null.

Implements [Matrix< T\\_ >](#).

```
int solve ( const Vect< T_ > & b, Vect< T_ > & x, bool fact = false ) [virtual]
```

Solve linear system.

The linear system having the current instance as a matrix is solved by using the LU decomposition. Solution is thus realized after a factorization step and a forward/backward substitution step. The factorization step is realized only if this was not already done.

Note that this function modifies the matrix contents if a factorization is performed. Naturally, if the matrix has been modified after using this function, the user has to refactorize it using the function `setLU`. This is because the class has no non-expensive way to detect if the matrix has been modified. The function `setLU` realizes the factorization step only.

Parameters

in	<i>b</i>	<a href="#">Vect</a> instance that contains right-hand side.
out	<i>x</i>	<a href="#">Vect</a> instance that contains solution
in	<i>fact</i>	Unused argument

Returns

- 0 if solution was normally performed,
- *n* if the *n*-th pivot is null.

Implements [Matrix< T\\_ >](#).

## 7.5 Brick Class Reference

To store and treat a brick (parallelepiped) figure.

Inheritance diagram for Brick:

Collaboration diagram for Brick:

## Public Member Functions

- **Brick** ()  
*Default constructor.*
- **Brick** (const **Point**< **real\_t** > &bbm, const **Point**< **real\_t** > &bbM, int code=1)  
*Constructor.*
- void **setBoundingBox** (const **Point**< **real\_t** > &bbm, const **Point**< **real\_t** > &bbM)  
*Assign bounding box of the brick.*
- **Point**< **real\_t** > **getBoundingBox1** () const  
*Return first point of bounding box (xmin,ymin,zmin)*
- **Point**< **real\_t** > **getBoundingBox2** () const  
*Return second point of bounding box (xmax,ymax,zmax)*
- **real\_t** **getSignedDistance** (const **Point**< **real\_t** > &p) const  
*Return signed distance of a given point from the current brick.*
- **Brick** & **operator+=** (**Point**< **real\_t** > a)  
*Operator +=.*
- **Brick** & **operator+=** (**real\_t** a)  
*Operator \*+=.*

### 7.5.1 Detailed Description

To store and treat a brick (parallelepiped) figure.

### 7.5.2 Constructor & Destructor Documentation

**Brick ( const Point< real.t > & *bbm*, const Point< real.t > & *bbM*, int *code* = 1 )**

Constructor.

Parameters

in	<i>bbm</i>	first point (xmin,ymin,zmin)
in	<i>bbM</i>	second point (xmax,ymax,zmax)
in	<i>code</i>	Code to assign to rectangle

### 7.5.3 Member Function Documentation

**void setBoundingBox ( const Point< real.t > & *bbm*, const Point< real.t > & *bbM* )**

Assign bounding box of the brick.

Parameters

in	<i>bbm</i>	first point (xmin,ymin,zmin)
in	<i>bbM</i>	second point (xmax,ymax,zmax)

**real.t getSignedDistance ( const Point< real.t > & *p* ) const** [virtual]

Return signed distance of a given point from the current brick.

The computed distance is negative if p lies in the brick, negative if it is outside, and 0 on its boundary

Parameters

in	<i>p</i>	Point<double> instance
----	----------	------------------------

Reimplemented from [Figure](#).

**Brick& operator+= ( Point< real.t > *a* )**

Operator +=.

Translate brick by a vector a

**Brick& operator+= ( real.t *a* )**

Operator \*+=.

Scale brick by a factor a

## 7.6 Circle Class Reference

To store and treat a circular figure.

Inheritance diagram for Circle:

Collaboration diagram for Circle:

## Public Member Functions

- `Circle ()`  
*Default constructor.*
- `Circle (const Point< real.t > &c, real.t r, int code=1)`  
*Constructor.*
- `void setRadius (real.t r)`  
*Assign radius of circle.*
- `real.t getRadius () const`  
*Return radius of circle.*
- `void setCenter (const Point< real.t > &c)`  
*Assign coordinates of center of circle.*
- `Point< real.t > getCenter () const`  
*Return coordinates of center of circle.*
- `real.t getSignedDistance (const Point< real.t > &p) const`  
*Return signed distance of a given point from the current circle.*
- `Circle & operator+= (Point< real.t > a)`

Operator +=.

- **Circle** & **operator+=** ( **real.t** a )

Operator \*+=.

### 7.6.1 Detailed Description

To store and treat a circular figure.

### 7.6.2 Constructor & Destructor Documentation

**Circle** ( **const Point**< **real.t** > & *c*, **real.t** *r*, **int** *code* = 1 )

Constructor.

Parameters

<b>in</b>	<i>c</i>	Coordinates of center of circle
<b>in</b>	<i>r</i>	Radius
<b>in</b>	<i>code</i>	Code to assign to the generated domain [Default: 1]

### 7.6.3 Member Function Documentation

**real.t** **getSignedDistance** ( **const Point**< **real.t** > & *p* ) **const** [virtual]

Return signed distance of a given point from the current circle.

The computed distance is negative if p lies in the disk, positive if it is outside, and 0 on the circle

Parameters

<b>in</b>	<i>p</i>	<b>Point</b> < <b>double</b> > instance
-----------	----------	---

Reimplemented from [Figure](#).

**Circle**& **operator+=** ( **Point**< **real.t** > *a* )

Operator +=.

Translate circle by a vector a

**Circle**& **operator+=** ( **real.t** *a* )

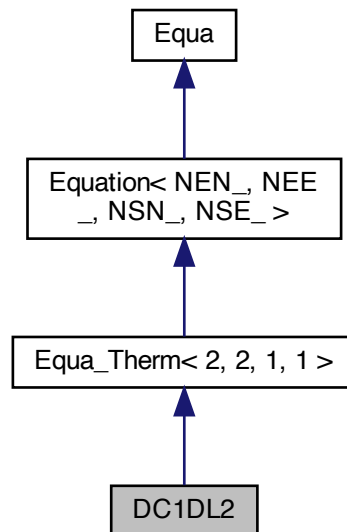

Operator \*+=.

Scale circle by a factor a

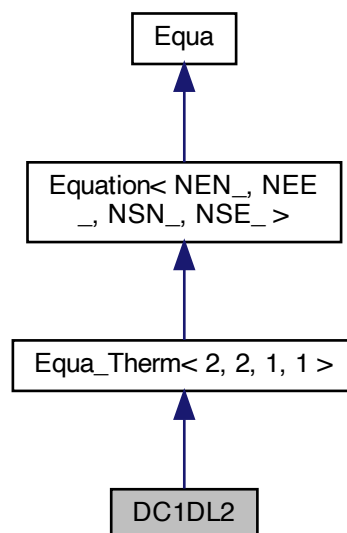

## 7.7 DC1DL2 Class Reference

Builds finite element arrays for thermal diffusion and convection in 1-D using 2-Node elements.

Inheritance diagram for DC1DL2:

Collaboration diagram for DC1DL2:

## Public Member Functions

- **DC1DL2** ()  
*Default Constructor.*

- void **BodyRHS** (const **Vect**< **real\_t** > &f)  
*Add body right-hand side term to right hand side.*
- **real\_t Flux** () const  
*Return (constant) heat flux in element.*
- void **setInput** (EqDataType opt, **Vect**< **real\_t** > &u)  
*Set equation input data.*

## Additional Inherited Members

### 7.7.1 Detailed Description

Builds finite element arrays for thermal diffusion and convection in 1-D using 2-Node elements.

Note that members calculating element arrays have as an argument a real coef that will be multiplied by the contribution of the current element. This makes possible testing different algorithms.

### 7.7.2 Constructor & Destructor Documentation

#### **DC1DL2** ( )

Default Constructor.

Constructs an empty equation.

#### **DC1DL2** ( **Mesh** & ms )

Constructor using mesh instance

Parameters

<code>in</code>	<code>ms</code>	<a href="#">Mesh</a> instance
-----------------	-----------------	-------------------------------

**DC1DL2 ( [Mesh](#) & *ms*, [Vect](#)< `real_t` > & *u* )**

Constructor using mesh instance and solution vector

Parameters

<code>in</code>	<code>ms</code>	<a href="#">Mesh</a> instance
<code>in, out</code>	<code>u</code>	<a href="#">Vect</a> instance containing solution vector

### 7.7.3 Member Function Documentation

**void LCapacity ( `real_t coef = 1` ) [virtual]**

Add lumped capacity matrix to element matrix after multiplying it by coefficient `coef`

Parameters

<code>in</code>	<code>coef</code>	Coefficient to multiply by added term [default: 1]
-----------------	-------------------	--

Reimplemented from [Equa\\_Therm](#)< 2, 2, 1, 1 >.

**void Capacity ( `real_t coef = 1` ) [virtual]**

Add Consistent capacity matrix to element matrix after multiplying it by coefficient `coef`.

Parameters

<code>in</code>	<code>coef</code>	Coefficient to multiply by added term [default: 1]
-----------------	-------------------	--

Reimplemented from [Equa\\_Therm](#)< 2, 2, 1, 1 >.

**void Diffusion ( `real_t coef = 1` ) [virtual]**

Add diffusion matrix to element matrix after multiplying it by coefficient `coef`

Parameters

<code>in</code>	<code>coef</code>	Coefficient to multiply by added term [default: 1]
-----------------	-------------------	--

Reimplemented from [Equa\\_Therm](#)< 2, 2, 1, 1 >.

**void Convection ( `const real_t & v`, `real_t coef = 1` )**

Add convection matrix to element matrix after multiplying it by coefficient `coef`

Parameters

<code>in</code>	<code>v</code>	Constant velocity vector
<code>in</code>	<code>coef</code>	Coefficient to multiply by added term [default: 1]

**void Convection ( `const Vect< real_t > & v, real_t coef = 1 )`**

Add convection matrix to element matrix after multiplying it by coefficient `coef`

Case where velocity field is given by a vector *v*

Parameters

in	$v$	Velocity vector
in	$coef$	Coefficient to multiply by added term [default: 1]

**void Convection ( real\_t coef = 1 ) [virtual]**

Add convection matrix to element matrix after multiplying it by coefficient  $coef$

Case where velocity field has been previously defined

Parameters

in	$coef$	Coefficient to multiply by added term [default: 1]
----	--------	--

Reimplemented from [Equa\\_Therm< 2, 2, 1, 1 >](#).

**void BodyRHS ( const Vect< real\_t > &f ) [virtual]**

Add body right-hand side term to right hand side.

Parameters

in	$f$	Vector containing source at nodes.
----	-----	------------------------------------

Reimplemented from [Equa\\_Therm< 2, 2, 1, 1 >](#).

**void setInput ( EqDataType opt, Vect< real\_t > &u )**

Set equation input data.

Parameters

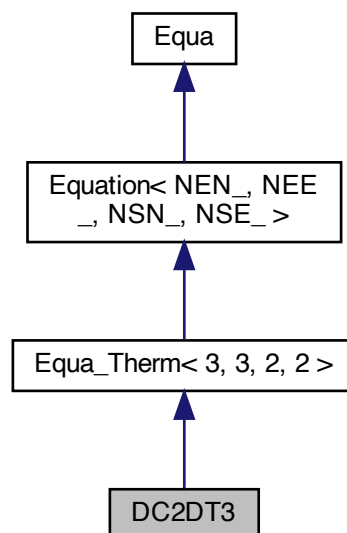

in	$opt$	<p>Parameter that selects data type for input. This parameter is to be chosen in the enumerated variable EqDataType</p> <ul style="list-style-type: none"> <li>• INITIAL_FIELD: Initial temperature</li> <li>• BOUNDARY_CONDITION_DATA: Boundary condition (Dirichlet)</li> <li>• SOURCE_DATA: Heat source</li> <li>• FLUX_DATA: Heat flux (Neumann boundary condition)</li> <li>• VELOCITY: Velocity vector (for the convection term)</li> </ul>
----	-------	---

<code>in</code>	<code>u</code>	Vector containing input data
-----------------	----------------	------------------------------

## 7.8 DC2DT3 Class Reference

- void `JouleHeating` (const `Vect< real_t >` &sigma, const `Vect< real_t >` &psi)

*Set Joule heating term as source.*

## Additional Inherited Members

### 7.8.1 Detailed Description

Builds finite element arrays for thermal diffusion and convection in 2-D domains using 3-Node triangles.

Note that members calculating element arrays have as an argument a real coef that will be multiplied by the contribution of the current element. This makes possible testing different algorithms.

### 7.8.2 Constructor & Destructor Documentation

**DC2DT3 ( Mesh & ms )**

Constructor using `Mesh` data.

Parameters

<code>in</code>	<code>ms</code>	<code>Mesh</code> instance
-----------------	-----------------	----------------------------

**DC2DT3 ( Mesh & ms, Vect< real\_t > & u )**

Constructor using `Mesh` and initial condition.

Parameters

<code>in</code>	<code>ms</code>	<a href="#">Mesh</a> instance
<code>in</code>	<code>u</code>	<a href="#">Vect</a> instance containing initial solution

### 7.8.3 Member Function Documentation

**void LCapacity ( `real.t coef = 1` )** [virtual]

Add lumped capacity matrix to element matrix after multiplying it by coefficient `coef`

Parameters

<code>in</code>	<code>coef</code>	Coefficient to multiply by added term [Default: 1].
-----------------	-------------------	---

Reimplemented from [Equa.Therm< 3, 3, 2, 2 >](#).

**void Capacity ( `real.t coef = 1` )** [virtual]

Add Consistent capacity matrix to element matrix after multiplying it by coefficient `coef`

Parameters

<code>in</code>	<code>coef</code>	Coefficient to multiply by added term [Default: 1]
-----------------	-------------------	--

Reimplemented from [Equa.Therm< 3, 3, 2, 2 >](#).

**void Diffusion ( `real.t coef = 1` )** [virtual]

Add diffusion matrix to element matrix after multiplying it by coefficient `coef`

Parameters

<code>in</code>	<code>coef</code>	Coefficient to multiply by added term [Default: 1]
-----------------	-------------------	--

Reimplemented from [Equa.Therm< 3, 3, 2, 2 >](#).

**void Diffusion ( `const LocalMatrix< real.t, 2, 2 > & diff, real.t coef = 1` )**

Add diffusion matrix to element matrix after multiplying it by coefficient `coef`

Case where the diffusivity matrix is given as an argument.

Parameters

<code>in</code>	<code>diff</code>	Diffusion matrix (class <a href="#">LocalMatrix</a> ).
<code>in</code>	<code>coef</code>	Coefficient to multiply by added term [Default: 1]

**void Convection ( `const Point< real.t > & v, real.t coef = 1` )**

Add convection matrix to element matrix after multiplying it by coefficient `coef`

Parameters

<code>in</code>	<code>v</code>	Constant velocity vector
<code>in</code>	<code>coef</code>	Coefficient to multiply by added term [Default: 1]

**void Convection ( `const Vect< real.t > & v, real.t coef = 1` )**

Add convection matrix to element matrix after multiplying it by coefficient `coef`

Case where velocity field is given by a vector `v`

Parameters

in	$v$	Velocity vector
in	$coef$	Coefficient to multiply by added term (Default: 1]

**void Convection ( real\_t coef = 1 ) [virtual]**

Add convection matrix to element matrix after multiplying it by coefficient  $coef$

Case where velocity field has been previously defined

Parameters

in	$coef$	Coefficient to multiply by added term [Default: 1]
----	--------	--

Reimplemented from [Equa\\_Therm< 3, 3, 2, 2 >](#).

**void LinearExchange ( real\_t coef, real\_t T )**

Add an edge linear exchange term to left and right-hand sides.

Parameters

in	$coef$	Coefficient of exchange
in	$T$	External value for exchange

Remarks

This assumes a constant value of T

**void BodyRHS ( const Vect< real\_t > &f ) [virtual]**

Add body right-hand side term to right hand side.

Parameters

in	$f$	Vector containing source at nodes.
----	-----	------------------------------------

Reimplemented from [Equa\\_Therm< 3, 3, 2, 2 >](#).

**void BodyRHS ( real\_t f )**

Add body right-hand side term to right hand side.

Case where the body right-hand side is piecewise constant.

Parameters

in	$f$	Value of thermal source (Constant in element).
----	-----	--

**void BoundaryRHS ( real\_t flux )**

Add boundary right-hand side flux to right hand side.

Parameters

in	$flux$	Vector containing source at side nodes.
----	--------	---

**void BoundaryRHS ( const Vect< real\_t > &f ) [virtual]**

Add boundary right-hand side term to right hand side after multiplying it by coefficient  $coef$

Parameters

<b>in</b>	<i>f</i>	Vector containing source at nodes
-----------	----------	-----------------------------------

Reimplemented from [Equa.Therm< 3, 3, 2, 2 >](#).

**void Periodic ( real.t coef = 1.e20 )**

Add contribution of periodic boundary condition (by a penalty technique).

Boundary nodes where periodic boundary conditions are to be imposed must have codes equal to PERIODIC.A on one side and PERIODIC.B on the opposite side.

Parameters

<b>in</b>	<i>coef</i>	Value of penalty parameter [Default: 1.e20]
-----------	-------------	---

**void Grad ( Vect< Point< real.t > > &g )**

Compute gradient of solution.

Parameters

<b>in</b>	<i>g</i>	Elementwise vector containing gradient of solution.
-----------	----------	---

**Point<real.t>& Grad ( const Vect< real.t > &u ) const**

Return gradient of a vector in element.

Parameters

<b>in</b>	<i>u</i>	Global vector for which gradient is computed. Vector u has as size the total number of nodes
-----------	----------	--

**void setInput ( EqDataType opt, Vect< real.t > &u )**

Set equation input data.

Parameters

<b>in</b>	<i>opt</i>	Parameter to select type of input (enumerated values) <ul style="list-style-type: none"> <li>INITIAL_FIELD: Initial temperature</li> <li>BOUNDARY_CONDITION_DATA: Boundary condition (Dirichlet)</li> <li>SOURCE_DATA: Heat source</li> <li>FLUX_DATA: Heat flux (Neumann boundary condition)</li> <li>VELOCITY_FIELD: Velocity vector (for the convection term)</li> </ul>
-----------	------------	---

<code>in</code>	<code>u</code>	Vector containing input data
-----------------	----------------	------------------------------

**void JouleHeating ( const Vect< real\_t > & *sigma*, const Vect< real\_t > & *psi* )**

Set Joule heating term as source.

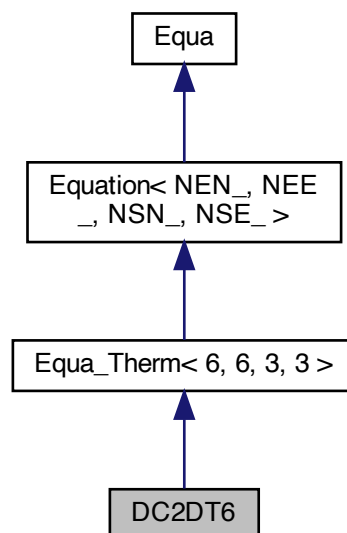

Parameters

<code>in</code>	<code>sigma</code>	<a href="#">Vect</a> instance containing electric conductivity (elementwise)
<code>in</code>	<code>psi</code>	<a href="#">Vect</a> instance containing electric potential (elementwise)

### 7.9.1 Detailed Description

Builds finite element arrays for thermal diffusion and convection in 2-D domains using 6-Node triangles.

Note that members calculating element arrays have as an argument a real *coef* that will be multiplied by the contribution of the current element. This makes possible testing different algorithms.

### 7.9.2 Constructor & Destructor Documentation

**DC2DT6 ( )**

Default Constructor.

Constructs an empty equation.

**DC2DT6 ( [Mesh](#) & *ms* )**

Constructor using [Mesh](#) data.

Parameters

<i>in</i>	<i>ms</i>	<a href="#">Mesh</a> instance
-----------	-----------	-------------------------------

**DC2DT6 ( [Mesh](#) & *ms*, [Vect](#)< [real\\_t](#) > & *u* )**

Constructor using [Mesh](#) data and solution vector.

Parameters

<i>in</i>	<i>ms</i>	<a href="#">Mesh</a> instance
<i>in,out</i>	<i>u</i>	<a href="#">Vect</a> instance containing solution vector

### 7.9.3 Member Function Documentation

**void LCapacity ( [real\\_t](#) *coef* = 1 ) [virtual]**

Add lumped capacity matrix to element matrix after multiplying it by coefficient *coef*.

Parameters

<i>in</i>	<i>coef</i>	Coefficient to multiply by added term (default value = 1).
-----------	-------------	--

Reimplemented from [Equa\\_Therm](#)< 6, 6, 3, 3 >.

**void Capacity ( [real\\_t](#) *coef* = 1 ) [virtual]**

Add Consistent capacity matrix to element matrix after multiplying it by coefficient *coef*.

Parameters

<b>in</b>	<i>coef</i>	Coefficient to multiply by added term (default value = 1).
-----------	-------------	--

Reimplemented from [Equa.Therm< 6, 6, 3, 3 >](#).

**void Diffusion ( real\_t coef = 1 )** [virtual]

Add diffusion matrix to element matrix after multiplying it by coefficient *coef*

Parameters

<b>in</b>	<i>coef</i>	Coefficient to multiply by added term [Default: 1].
-----------	-------------	---

Reimplemented from [Equa.Therm< 6, 6, 3, 3 >](#).

**void Convection ( real\_t coef = 1 )** [virtual]

Add convection matrix to left-hand side after multiplying it by coefficient *coef*

Case where velocity field has been previously defined

Parameters

<b>in</b>	<i>coef</i>	Coefficient to multiply by added term [Default: 1].
-----------	-------------	---

Reimplemented from [Equa.Therm< 6, 6, 3, 3 >](#).

**void Convection ( Point< real\_t > &v, real\_t coef = 1 )**

Add convection matrix to left hand side after multiplying it by coefficient *coef*

Parameters

<b>in</b>	<i>v</i>	Constant velocity vector.
<b>in</b>	<i>coef</i>	Coefficient to multiply by added term [Default: 1].

**void Convection ( const Vect< real\_t > &v, real\_t coef = 1 )**

Add convection matrix to left-hand side after multiplying it by coefficient *coef*

Case where velocity field is given by a vector *v*

Parameters

<b>in</b>	<i>v</i>	Velocity vector.
<b>in</b>	<i>coef</i>	Coefficient to multiply by added term [Default: 1].

**void BodyRHS ( const Vect< real\_t > &f )** [virtual]

Add body right-hand side term to right hand side.

Parameters

<b>in</b>	<i>f</i>	Local vector (of size 6) containing source at nodes
-----------	----------	---

Reimplemented from [Equa.Therm< 6, 6, 3, 3 >](#).

**void BoundaryRHS ( const Vect< real\_t > &f )** [virtual]

Add boundary right-hand side term to right hand side after multiplying it by coefficient *coef*

Parameters

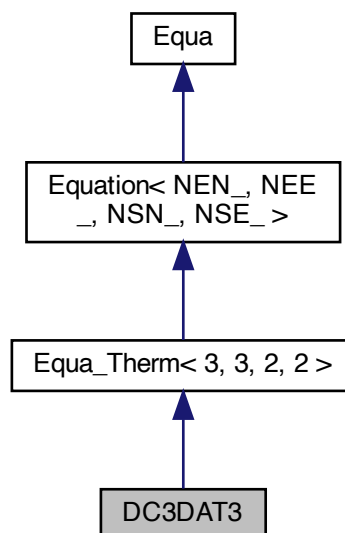

<code>in</code>	<code>f</code>	Vector containing source at nodes
-----------------	----------------	-----------------------------------

Reimplemented from [Equa\\_Therm< 6, 6, 3, 3 >](#).

### 7.10.1 Detailed Description

Builds finite element arrays for thermal diffusion and convection in 3-D domains with axisymmetry using 3-Node triangles.

Note that members calculating element arrays have as an argument a real `coef` that will be multiplied by the contribution of the current element. This makes possible testing different algorithms.

### 7.10.2 Constructor & Destructor Documentation

#### DC3DAT3 ( )

Default Constructor.

Constructs an empty equation.

#### DC3DAT3 ( Mesh & *ms* )

Constructor using `Mesh` data.

Parameters

<code>in</code>	<code>ms</code>	<code>Mesh</code> instance
-----------------	-----------------	----------------------------

#### DC3DAT3 ( Mesh & *ms*, Vect< real.t > & *u* )

Constructor using `Mesh` data and solution vector.

Parameters

<code>in</code>	<code>ms</code>	<code>Mesh</code> instance
<code>in,out</code>	<code>u</code>	<code>Vect</code> instance containing solution vector

### 7.10.3 Member Function Documentation

#### void LCapacity ( real.t *coef* = 1 ) [virtual]

Add lumped capacity matrix to element matrix after multiplying it by coefficient `coef`.

Parameters

<code>in</code>	<code>coef</code>	Coefficient to multiply by added term [Default: 1].
-----------------	-------------------	---

Reimplemented from `Equa.Therm< 3, 3, 2, 2 >`.

#### void Capacity ( real.t *coef* = 1 ) [virtual]

Add Consistent capacity matrix to element matrix after multiplying it by coefficient `coef`

Parameters

<b>in</b>	<i>coef</i>	Coefficient to multiply by added term [Default: 1].
-----------	-------------	---

Reimplemented from [Equa.Therm< 3, 3, 2, 2 >](#).

**void Diffusion ( real.t coef = 1 )** [virtual]

Add diffusion matrix to left-hand side after multiplying it by coefficient *coef*

Parameters

<b>in</b>	<i>coef</i>	Coefficient to multiply by added term [Default: 1].
-----------	-------------	---

Reimplemented from [Equa.Therm< 3, 3, 2, 2 >](#).

**void Diffusion ( const LocalMatrix< real.t, 2, 2 > &diff, real.t coef = 1 )**

Add diffusion matrix to left-hand side after multiplying it by coefficient *coef*

Case where the diffusivity matrix is given as an argument

Parameters

<b>in</b>	<i>diff</i>	Instance of class <a href="#">DMatrix</a> containing diffusivity matrix
<b>in</b>	<i>coef</i>	Coefficient to multiply by added term [Default: 1]

**void BodyRHS ( const Vect< real.t > &f )** [virtual]

Add body right-hand side term to right hand side.

Parameters

<b>in</b>	<i>f</i>	Local vector (of size 3) containing source at odes.
-----------	----------	---

Reimplemented from [Equa.Therm< 3, 3, 2, 2 >](#).

**void BoundaryRHS ( real.t flux )**

Add boundary right-hand side term to right hand side.

Parameters

<b>in</b>	<i>flux</i>	Value of flux to impose on the side
-----------	-------------	-------------------------------------

**void BoundaryRHS ( const Vect< real.t > &f )** [virtual]

Add boundary right-hand side term to right hand side after multiplying it by coefficient *coef*

Parameters

<b>in</b>	<i>f</i>	Vector containing source at nodes
-----------	----------	-----------------------------------

Reimplemented from [Equa.Therm< 3, 3, 2, 2 >](#).

**Point<real.t>& Grad ( const Vect< real.t > &u )**

Return gradient of a vector in element.

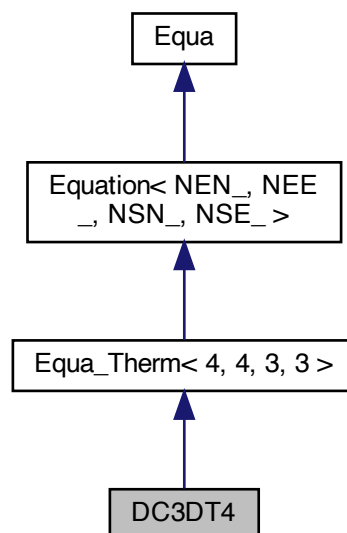

Parameters

<b>in</b>	<i>u</i>	Vector for which gradient is computed.
-----------	----------	--

Parameters

<code>in</code>	<code>ms</code>	<code>Mesh</code> instance
-----------------	-----------------	----------------------------

#### DC3DT4 ( Mesh & *ms*, Vect< real.t > & *u* )

Constructor using `Mesh` and initial condition.

Parameters

<code>in</code>	<code>ms</code>	<code>Mesh</code> instance
<code>in</code>	<code>u</code>	<code>Vect</code> instance containing initial solution

### 7.11.3 Member Function Documentation

`void LCapacity` ( `real.t coef = 1` ) [virtual]

Add lumped capacity matrix to element matrix after multiplying it by coefficient `coef`

Parameters

<b>in</b>	<i>coef</i>	Coefficient to multiply by added term [Default: 1].
-----------	-------------	---

Reimplemented from [Equa.Therm< 4, 4, 3, 3 >](#).

**void Capacity ( real\_t coef = 1 ) [virtual]**

Add consistent capacity matrix to element matrix after multiplying it by coefficient *coef*

Parameters

<b>in</b>	<i>coef</i>	Coefficient to multiply by added term [Default: 1].
-----------	-------------	---

Reimplemented from [Equa.Therm< 4, 4, 3, 3 >](#).

**void Diffusion ( real\_t coef = 1 ) [virtual]**

Add diffusion matrix to element matrix after multiplying it by coefficient *coef*.

Parameters

<b>in</b>	<i>coef</i>	Coefficient to multiply by added term (default value = 1).
-----------	-------------	--

Reimplemented from [Equa.Therm< 4, 4, 3, 3 >](#).

**void Diffusion ( const DMatrix< real\_t > & diff, real\_t coef = 1 )**

Add diffusion matrix to element matrix after multiplying it by coefficient *coef*

Case where the diffusivity matrix is given as an argument.

Parameters

<b>in</b>	<i>diff</i>	Diffusion matrix (class <a href="#">DMatrix</a> ).
<b>in</b>	<i>coef</i>	Coefficient to multiply by added term [Default: 1].

**void Convection ( real\_t coef = 1 ) [virtual]**

Add convection matrix to element matrix after multiplying it by coefficient *coef*

Case where velocity field has been previously defined

Parameters

<b>in</b>	<i>coef</i>	Coefficient to multiply by added term [Default: 1].
-----------	-------------	---

Reimplemented from [Equa.Therm< 4, 4, 3, 3 >](#).

**void Convection ( const Point< real\_t > & v, real\_t coef = 1 )**

Add convection matrix to element matrix after multiplying it by coefficient *coef*

Parameters

<b>in</b>	<i>v</i>	Constant velocity vector
<b>in</b>	<i>coef</i>	Coefficient to multiply by added term [Default: 1].

**void Convection ( const Vect< Point< real\_t > > & v, real\_t coef = 1 )**

Add convection matrix to element matrix after multiplying it by coefficient *coef*

Case where velocity field is given by a vector *v*.

Parameters

<b>in</b>	<i>v</i>	Velocity vector.
<b>in</b>	<i>coef</i>	Coefficient to multiply by added term [Default: 1].

**void BodyRHS ( const Vect< real.t > &f )** [virtual]

Add body right-hand side term to right hand side.

Parameters

<b>in</b>	<i>f</i>	Vector containing source at nodes.
-----------	----------	------------------------------------

Reimplemented from [Equa.Therm< 4, 4, 3, 3 >](#).

**void BoundaryRHS ( const Vect< real.t > &f )** [virtual]

Add boundary right-hand side term to right hand side after multiplying it by coefficient *coef*

Case where body source is given by a vector

Parameters

<b>in</b>	<i>f</i>	Vector containing source at nodes.
-----------	----------	------------------------------------

Reimplemented from [Equa.Therm< 4, 4, 3, 3 >](#).

**void BoundaryRHS ( real.t flux )**

Add boundary right-hand side flux to right hand side.

Parameters

<b>in</b>	<i>flux</i>	Vector containing source at side nodes.
-----------	-------------	---

**void Grad ( Vect< Point< real.t > > &g )**

Compute gradient of solution.

Parameters

<b>in</b>	<i>g</i>	Elementwise vector containing gradient of solution.
-----------	----------	---

**void Periodic ( real.t coef = 1.e20 )**

Add contribution of periodic boundary condition (by a penalty technique).

Boundary nodes where periodic boundary conditions are to be imposed must have codes equal to PERIODIC\_A on one side and PERIODIC\_B on the opposite side.

Parameters

<b>in</b>	<i>coef</i>	Value of penalty parameter [Default: 1.e20].
-----------	-------------	--

### 7.13.1 Detailed Description

**template<class T\_>class OFELI::DMatrix< T\_ >**

To handle dense matrices.

This class enables storing and manipulating general dense matrices. Matrices can be square or rectangle ones.

Template Parameters

<code>T_</code>	Data type (double, float, complex<double>, ...)
-----------------	---

Author

Rachid Touzani

Copyright

GNU Lesser Public License

### 7.13.2 Constructor & Destructor Documentation

**DMatrix ( )**

Default constructor.

Initializes a zero-dimension matrix.

**DMatrix ( size\_t nr )**

Constructor for a matrix with nr rows and nr columns.

Matrix entries are set to 0.

**DMatrix ( size\_t nr, size\_t nc )**

Constructor for a matrix with nr rows and nc columns.

[Matrix](#) entries are set to 0.

**DMatrix ( Vect< T\_ > & v )**

Constructor that uses a [Vect](#) instance. The class uses the memory space occupied by this vector.

Parameters

in	<i>v</i>	Vector to copy
----	----------	----------------

**DMatrix ( const DMatrix< T\_ > & m )**

Copy Constructor.

Parameters

in	<i>m</i>	Matrix to copy
----	----------	----------------

**DMatrix ( Mesh & mesh, size\_t dof = 0, int is\_diagonal = false )**

Constructor using mesh to initialize structure of matrix.

Parameters

in	<i>mesh</i>	<a href="#">Mesh</a> instance for which matrix graph is determined.
in	<i>dof</i>	Option parameter, with default value 0. dof=1 means that only one degree of freedom for each node (or element or side) is taken to determine matrix structure. The value dof=0 means that matrix structure is determined using all DOFs.
in	<i>is_diagonal</i>	Boolean argument to say is the matrix is actually a diagonal matrix or not.

**7.13.3 Member Function Documentation****void setDiag ( const T\_ & a )**

Set matrix as diagonal and assign its diagonal entries as a constant.

Parameters

in	<i>a</i>	Value to assign to all diagonal entries
----	----------	---

**void setDiag ( const vector< T\_ > & d )**

Set matrix as diagonal and assign its diagonal entries.

Parameters

in	<i>d</i>	Vector entries to assign to matrix diagonal entries
----	----------	---

**void setSize ( size\_t size )**

Set size (number of rows) of matrix.

Parameters

<b>in</b>	<i>size</i>	Number of rows and columns.
-----------	-------------	-----------------------------

**void setSize ( size\_t *nr*, size\_t *nc* )**

Set size (number of rows and columns) of matrix.

Parameters

<b>in</b>	<i>nr</i>	Number of rows.
<b>in</b>	<i>nc</i>	Number of columns.

**void getColumn ( size\_t *j*, Vect< T\_ > & *v* ) const**

Get *j*-th column vector.

Parameters

<b>in</b>	<i>j</i>	Index of column to extract
<b>out</b>	<i>v</i>	Reference to <a href="#">Vect</a> instance where the column is stored

Remarks

Vector *v* does not need to be sized before. It is resized in the function

**Vect<T\_> getColumn ( size\_t *j* ) const**

Get *j*-th column vector.

Parameters

<b>in</b>	<i>j</i>	Index of column to extract
-----------	----------	----------------------------

Returns

[Vect](#) instance where the column is stored

Remarks

Vector *v* does not need to be sized before. It is resized in the function

**void getRow ( size\_t *i*, Vect< T\_ > & *v* ) const**

Get *i*-th row vector.

Parameters

<b>in</b>	<i>i</i>	Index of row to extract
<b>out</b>	<i>v</i>	Reference to <a href="#">Vect</a> instance where the row is stored

Remarks

Vector *v* does not need to be sized before. It is resized in the function

**Vect<T\_> getRow ( size\_t *i* ) const**

Get *i*-th row vector.

Parameters

in	<i>i</i>	Index of row to extract
----	----------	-------------------------

Returns

[Vect](#) instance where the row is stored

Remarks

Vector *v* does not need to be sized before. It is resized in the function

**void set ( size\_t *i*, size\_t *j*, const T\_ & *val* )** [virtual]

Assign a constant value to an entry of the matrix.

Parameters

in	<i>i</i>	row index of matrix
in	<i>j</i>	column index of matrix
in	<i>val</i>	Value to assign to <i>a</i> ( <i>i</i> , <i>j</i> ).

Implements [Matrix< T\\_ >](#).

**void reset ( )** [virtual]

Set matrix to 0 and reset factorization parameter.

Warning

This function must be used if after a factorization, the matrix has modified

Reimplemented from [Matrix< T\\_ >](#).

**void setRow ( size\_t *i*, const Vect< T\_ > & *v* )**

Copy a given vector to a prescribed row in the matrix.

Parameters

in	<i>i</i>	row index to be assigned
in	<i>v</i>	<a href="#">Vect</a> instance to copy

**void setColumn ( size\_t *j*, const Vect< T\_ > & *v* )**

Copy a given vector to a prescribed column in the matrix.

Parameters

in	<i>j</i>	column index to be assigned
in	<i>v</i>	<a href="#">Vect</a> instance to copy

**void MultAdd ( T\_ *a*, const Vect< T\_ > & *x*, Vect< T\_ > & *y* ) const** [virtual]

Multiply matrix by vector *a*\**x* and add result to *y*.

Parameters

in	$a$	constant to multiply by
in	$x$	Vector to multiply by $a$
in,out	$y$	on input, vector to add to. On output, result.

Implements [Matrix< T\\_ >](#).

**void MultAdd ( const Vect< T\_ > &  $x$ , Vect< T\_ > &  $y$  ) const** [virtual]

Multiply matrix by vector  $x$  and add result to  $y$ .

Parameters

in	$x$	Vector to add to $y$
in,out	$y$	on input, vector to add to. On output, result.

Implements [Matrix< T\\_ >](#).

**void Mult ( const Vect< T\_ > &  $x$ , Vect< T\_ > &  $y$  ) const** [virtual]

Multiply matrix by vector  $x$  and save result in  $y$ .

Parameters

in	$x$	Vector to add to $y$
out	$y$	Result.

Implements [Matrix< T\\_ >](#).

**void TMult ( const Vect< T\_ > &  $x$ , Vect< T\_ > &  $y$  ) const** [virtual]

Multiply transpose of matrix by vector  $x$  and add result in  $y$ .

Parameters

in	$x$	Vector to add to $y$
in,out	$y$	on input, vector to add to. On output, result.

Implements [Matrix< T\\_ >](#).

**void add ( size\_t  $i$ , size\_t  $j$ , const T\_ &  $val$  )** [virtual]

Add constant  $val$  to entry ( $i$ ,  $j$ ) of the matrix.

Parameters

in	$i$	row index
in	$j$	column index
in	$val$	Constant to add

Implements [Matrix< T\\_ >](#).

**void Axy ( T\_  $a$ , const DMatrix< T\_ > &  $m$  )**

Add to matrix the product of a matrix by a scalar.

Parameters

in	$a$	Scalar to premultiply
----	-----	-----------------------

<i>in</i>	<i>m</i>	Matrix by which <i>a</i> is multiplied. The result is added to current instance
-----------	----------	---

**void Axpy ( T\_ *a*, const Matrix< T\_ > \* *m* )** [virtual]

Add to matrix the product of a matrix by a scalar.

Parameters

<i>in</i>	<i>a</i>	Scalar to premultiply
<i>in</i>	<i>m</i>	Matrix by which <i>a</i> is multiplied. The result is added to current instance

Implements [Matrix< T\\_ >](#).

**int setQR ( )**

Construct a QR factorization of the matrix.

This function constructs the QR decomposition using the Householder method. The upper triangular matrix *R* is returned in the upper triangle of the current matrix, except for the diagonal elements of *R* which are stored in an internal vector. The orthogonal matrix *Q* is represented as a product of *n*-1 Householder matrices *Q*<sub>1</sub> . . . *Q*<sub>*n*-1</sub>, where *Q*<sub>*j*</sub> = 1 - *u<sub>j</sub>.u<sub>j</sub>* / *c<sub>j</sub>* . The *i*-th component of *u<sub>j</sub>* is zero for *i* = 1, ..., *j*-1 while the nonzero components are returned in *a*[*i*][*j*] for *i* = *j*, ..., *n*.

Returns

0 if the decomposition was successful, *k* is the *k*-th row is singular

Remarks

The matrix can be square or rectangle

**int setTransQR ( )**

Construct a QR factorization of the transpose of the matrix.

This function constructs the QR decomposition using the Householder method. The upper triangular matrix *R* is returned in the upper triangle of the current matrix, except for the diagonal elements of *R* which are stored in an internal vector. The orthogonal matrix *Q* is represented as a product of *n*-1 Householder matrices *Q*<sub>1</sub> . . . *Q*<sub>*n*-1</sub>, where *Q*<sub>*j*</sub> = 1 - *u<sub>j</sub>.u<sub>j</sub>* / *c<sub>j</sub>* . The *i*-th component of *u<sub>j</sub>* is zero for *i* = 1, ..., *j*-1 while the nonzero components are returned in *a*[*i*][*j*] for *i* = *j*, ..., *n*.

Returns

0 if the decomposition was successful, *k* is the *k*-th row is singular

Remarks

The matrix can be square or rectangle

**int solveQR ( const Vect< T\_ > & *b*, Vect< T\_ > & *x* )**

Solve a linear system by QR decomposition.

This function constructs the QR decomposition, if this was not already done by using the member function `QR` and solves the linear system

Parameters

in	$b$	Right-hand side vector
out	$x$	Solution vector. Must have been sized before using this function.

Returns

The same value as returned by the function QR

**int solveTransQR ( const Vect< T\_ > &  $b$ , Vect< T\_ > &  $x$  )**

Solve a transpose linear system by QR decomposition.

This function constructs the QR decomposition, if this was not already done by using the member function QR and solves the linear system

Parameters

in	$b$	Right-hand side vector
out	$x$	Solution vector. Must have been sized before using this function.

Returns

The same value as returned by the function QR

**T\_ operator() ( size\_t  $i$ , size\_t  $j$  ) const** [virtual]

Operator () (Constant version). Return  $a(i, j)$

Parameters

in	$i$	row index
in	$j$	column index

Implements [Matrix< T\\_ >](#).

**T\_& operator() ( size\_t  $i$ , size\_t  $j$  )** [virtual]

Operator () (Non constant version). Return  $a(i, j)$

Parameters

in	$i$	row index
in	$j$	column index

Implements [Matrix< T\\_ >](#).

**int setLU ( )**

Factorize the matrix (LU factorization)

LU factorization of the matrix is realized. Note that since this is an in place factorization, the contents of the matrix are modified.

Returns

- 0 if factorization was normally performed,
- $n$  if the  $n$ -th pivot is null.

Remarks

A flag in this class indicates after factorization that this one has been realized, so that, if the member function solve is called after this no further factorization is done.

**int setTransLU ( )**

Factorize the transpose of the matrix (LU factorization)

LU factorization of the transpose of the matrix is realized. Note that since this is an in place factorization, the contents of the matrix are modified.

Returns

- 0 if factorization was normally performed,
- n if the n-th pivot is null.

Remarks

A flag in this class indicates after factorization that this one has been realized, so that, if the member function solve is called after this no further factorization is done.

**int solve ( Vect< T\_ > & b, bool fact = true ) [virtual]**

Solve linear system.

The linear system having the current instance as a matrix is solved by using the LU decomposition. Solution is thus realized after a factorization step and a forward/backward substitution step. The factorization step is realized only if this was not already done.

Note that this function modifies the matrix contents is a factorization is performed. Naturally, if the the matrix has been modified after using this function, the user has to refactorize it using the function setLU. This is because the class has no non-expensive way to detect if the matrix has been modified. The function setLU realizes the factorization step only.

Parameters

in,out	<i>b</i>	Vect instance that contains right-hand side on input and solution on output.
in	<i>fact</i>	Set true if matrix is to be factorized (Default value), false if not

Returns

- 0 if solution was normally performed,
- n if the n-th pivot is null.

Implements [Matrix< T\\_ >](#).

**int solveTrans ( Vect< T\_ > & b, bool fact = true )**

Solve the transpose linear system.

The linear system having the current instance as a transpose matrix is solved by using the LU decomposition. Solution is thus realized after a factorization step and a forward/backward substitution step. The factorization step is realized only if this was not already done.

Note that this function modifies the matrix contents is a factorization is performed. Naturally, if the the matrix has been modified after using this function, the user has to refactorize it using the function setLU. This is because the class has no non-expensive way to detect if the matrix has been modified. The function setLU realizes the factorization step only.

Parameters

in,out	<i>b</i>	<a href="#">Vect</a> instance that contains right-hand side on input and solution on output.
in	<i>fact</i>	Set true if matrix is to be factorized (Default value), false if not

Returns

- 0 if solution was normally performed,
- *n* if the *n*-th pivot is null.

**int solve ( const Vect< T\_ > & *b*, Vect< T\_ > & *x*, bool *fact* = *true* )** [virtual]

Solve linear system.

The linear system having the current instance as a matrix is solved by using the LU decomposition. Solution is thus realized after a factorization step and a forward/backward substitution step. The factorization step is realized only if this was not already done.

Note that this function modifies the matrix contents is a factorization is performed. Naturally, if the the matrix has been modified after using this function, the user has to refactorize it using the function setLU. This is because the class has no non-expensive way to detect if the matrix has been modified. The function setLU realizes the factorization step only.

Parameters

in	<i>b</i>	<a href="#">Vect</a> instance that contains right-hand side.
out	<i>x</i>	<a href="#">Vect</a> instance that contains solution
in	<i>fact</i>	Set true if matrix is to be factorized (Default value), false if not

Returns

- 0 if solution was normally performed,
- *n* if the *n*-th pivot is null.

Implements [Matrix< T\\_ >](#).

**int solveTrans ( const Vect< T\_ > & *b*, Vect< T\_ > & *x*, bool *fact* = *true* )**

Solve the transpose linear system.

The linear system having the current instance as a transpose matrix is solved by using the LU decomposition. Solution is thus realized after a factorization step and a forward/backward substitution step. The factorization step is realized only if this was not already done.

Note that this function modifies the matrix contents is a factorization is performed. Naturally, if the the matrix has been modified after using this function, the user has to refactorize it using the function setLU. This is because the class has no non-expensive way to detect if the matrix has been modified. The function setLU realizes the factorization step only.

Parameters

in	<i>b</i>	<a href="#">Vect</a> instance that contains right-hand side.
out	<i>x</i>	<a href="#">Vect</a> instance that contains solution
in	<i>fact</i>	Set true if matrix is to be factorized (Default value), false if not

Returns

- 0 if solution was normally performed,
- *n* if the *n*-th pivot is null.

**DMatrix& operator= ( DMatrix< T\_ > & m )**

Operator =

Copy matrix *m* to current matrix instance.

**DMatrix& operator+= ( const DMatrix< T\_ > & m )**

Operator +=.

Add matrix *m* to current matrix instance.

**DMatrix& operator-= ( const DMatrix< T\_ > & m )**

Operator -=.

Subtract matrix *m* from current matrix instance.

**DMatrix& operator= ( const T\_ & x )**

Operator =

Assign matrix to identity times *x*

**DMatrix& operator\*= ( const T\_ & x )**

Operator \*=

Premultiply matrix entries by constant value *x*.

**DMatrix& operator+= ( const T\_ & x )**

Operator +=

Add constant value *x* to matrix entries

**DMatrix& operator-= ( const T\_ & x )**

Operator -=

Subtract constant value *x* from matrix entries.

**T\_\* getArray ( ) const**

Return matrix as C-Array.

Matrix is stored row by row.

### 7.14.1 Detailed Description

To store and treat finite element geometric information.

This class is essentially useful to construct data for mesh generators.

Author

Rachid Touzani

Copyright

GNU Lesser Public License

### 7.14.2 Constructor & Destructor Documentation

**Domain ( )**

Constructor of a null domain.

This constructor assigns maximal values of parameters.

**Domain ( const string & file )**

Constructor with an input file.

Parameters

---

<b>in</b>	<i>file</i>	Input file in the XML format defining the domain
-----------	-------------	--

### 7.14.3 Member Function Documentation

**void get ( const string & *file* )**

Read domain data from a data file.

Parameters

<b>in</b>	<i>file</i>	Input file in <a href="#">Domain</a> XML format
-----------	-------------	---

**void genMesh ( const string & *file* )**

Generate 2-D mesh and save in file ([OFELI](#) format)

Parameters

<b>in</b>	<i>file</i>	File where the generated mesh is saved
-----------	-------------	--

**void genMesh ( string *geo\_file*, string *bamg\_file*, string *mesh\_file* )**

Generate 2-D mesh and save geo, bamg and mesh file ([OFELI](#) format)

Parameters

<b>in</b>	<i>geo_file</i>	Geo file
<b>in</b>	<i>bamg_file</i>	Bamg file
<b>in</b>	<i>mesh_file</i>	File where the generated mesh is saved

**Domain& operator\*= ( real\_t *a* )**

Operator \*=

Rescale domain coordinates by multiplying by a factor

Parameters

<b>in</b>	<i>a</i>	Value to multiply by
-----------	----------	----------------------

**void insertVertex ( real\_t *x*, real\_t *y*, real\_t *h*, int *code* )**

Insert a vertex.

Parameters

<b>in</b>	<i>x</i>	x-coordinate of vertex
<b>in</b>	<i>y</i>	y-coordinate of vertex
<b>in</b>	<i>h</i>	mesh size around vertex
<b>in</b>	<i>code</i>	code of coordinate

**void insertVertex ( real\_t *x*, real\_t *y*, real\_t *z*, real\_t *h*, int *code* )**

Insert a vertex (3-D case)

Parameters

<b>in</b>	$x$	x-coordinate of vertex
<b>in</b>	$y$	y-coordinate of vertex
<b>in</b>	$z$	z-coordinate of vertex
<b>in</b>	$h$	mesh size around vertex
<b>in</b>	$code$	code of coordinate

**void insertLine ( size\_t  $n1$ , size\_t  $n2$ , int  $c$  )**

Insert a straight line.

Parameters

<b>in</b>	$n1$	Label of the first vertex of line
<b>in</b>	$n2$	Label of the second vertex of line
<b>in</b>	$c$	Code to associate to created nodes (Dirichlet) or sides (Neumann) if $< 0$

**void insertLine ( size\_t  $n1$ , size\_t  $n2$ , int  $dc$ , int  $nc$  )**

Insert a straight line.

Parameters

<b>in</b>	$n1$	Label of the first vertex of line
<b>in</b>	$n2$	Label of the second vertex of line
<b>in</b>	$dc$	Code to associate to created nodes (Dirichlet)
<b>in</b>	$nc$	Code to associate to created sides (Neumann)

**void insertCircle ( size\_t  $n1$ , size\_t  $n2$ , size\_t  $n3$ , int  $c$  )**

Insert a circluar arc.

Parameters

<b>in</b>	$n1$	Label of vertex defining the first end of the arc
<b>in</b>	$n2$	Label of vertex defining the second end of the arc
<b>in</b>	$n3$	Label of vertex defining the center of the arc
<b>in</b>	$c$	Code to associate to created nodes (Dirichlet) or sides (Neumann) if $< 0$

**void insertCircle ( size\_t  $n1$ , size\_t  $n2$ , size\_t  $n3$ , int  $dc$ , int  $nc$  )**

Insert a circluar arc.

Parameters

<b>in</b>	$n1$	Label of vertex defining the first end of the arc
<b>in</b>	$n2$	Label of vertex defining the second end of the arc
<b>in</b>	$n3$	Label of vertex defining the center of the arc
<b>in</b>	$dc$	Code to associate to created nodes (Dirichlet)

<code>in</code>	<code>nc</code>	Code to associate to created sides (Neumann)
-----------------	-----------------	--

**void insertRequiredVertex ( size\_t *v* )**

Insert a required (imposed) vertex.

Parameters

<code>in</code>	<code>v</code>	Label of vertex
-----------------	----------------	-----------------

**void insertRequiredEdge ( size\_t *e* )**

Insert a required (imposed) edge (or line)

Parameters

<code>in</code>	<code>e</code>	Label of line
-----------------	----------------	---------------

**void insertSubDomain ( size\_t *n*, int *code* )**

Insert subdomain.

Parameters

<code>in</code>	<code>n</code>	
<code>in</code>	<code>code</code>	

**void insertSubDomain ( size\_t *ln*, int *orient*, int *code* )**

Insert subdomain.

Parameters

<code>in</code>	<code>ln</code>	Line label
<code>in</code>	<code>orient</code>	Orientation (1 or -1)
<code>in</code>	<code>code</code>	Subdomain code or reference

**void setOutputFile ( string *file* )**

Define output mesh file.

Parameters

<code>in</code>	<code>file</code>	String defining output mesh file
-----------------	-------------------	----------------------------------

Return entry  $(i, j)$  of matrix.

### 7.15.1 Detailed Description

**template<class T\_>class OFELI::DSMatrix< T\_ >**

To handle symmetric dense matrices.

This class enables storing and manipulating symmetric dense matrices.

Template Parameters

<i>T_</i>	Data type (double, float, complex<double>, ...)
-----------	---

Author

Rachid Touzani

Copyright

GNU Lesser Public License

### 7.15.2 Constructor & Destructor Documentation

**DSMatrix ( size\_t dim )**

Constructor that for a symmetric matrix with given number of rows.

Parameters

<i>in</i>	<i>dim</i>	Number of rows
-----------	------------	----------------

**DSMatrix ( const DSMatrix< T\_ > & m )**

Copy Constructor.

Parameters

<i>in</i>	<i>m</i>	<a href="#">DSMatrix</a> instance to copy
-----------	----------	---

**DSMatrix ( Mesh & mesh, size\_t dof = 0, int is\_diagonal = false )**

Constructor using mesh to initialize matrix.

Parameters

<i>in</i>	<i>mesh</i>	<a href="#">Mesh</a> instance for which matrix graph is determined.
<i>in</i>	<i>dof</i>	Option parameter, with default value 0. dof=1 means that only one degree of freedom for each node (or element or side) is taken to determine matrix structure. The value dof=0 means that matrix structure is determined using all DOFs.
<i>in</i>	<i>is_diagonal</i>	Boolean argument to say is the matrix is actually a diagonal matrix or not.

### 7.15.3 Member Function Documentation

**void setSize ( size\_t *dim* )**

Set size (number of rows) of matrix.

Parameters

<b>in</b>	<i>dim</i>	Number of rows and columns.
-----------	------------	-----------------------------

**void set ( size\_t *i*, size\_t *j*, const T\_ & *val* )** [virtual]

Assign constant to entry (i,j) of the matrix.

Parameters

<b>in</b>	<i>i</i>	row index
<b>in</b>	<i>j</i>	column index
<b>in</b>	<i>val</i>	value to assign to a(i,j)

Implements [Matrix< T\\_ >](#).

**void getColumn ( size\_t *j*, Vect< T\_ > & *v* ) const**

Get j-th column vector.

Parameters

<b>in</b>	<i>j</i>	Index of column to extract
<b>out</b>	<i>v</i>	Reference to <a href="#">Vect</a> instance where the column is stored

Remarks

Vector v does not need to be sized before. It is resized in the function

**Vect<T\_> getColumn ( size\_t *j* ) const**

Get j-th column vector.

Parameters

<b>in</b>	<i>j</i>	Index of column to extract
-----------	----------	----------------------------

Returns

[Vect](#) instance where the column is stored

Remarks

Vector v does not need to be sized before. It is resized in the function

**void getRow ( size\_t *i*, Vect< T\_ > & *v* ) const**

Get i-th row vector.

Parameters

<b>in</b>	<i>i</i>	Index of row to extract
<b>out</b>	<i>v</i>	Reference to <a href="#">Vect</a> instance where the row is stored

Remarks

Vector v does not need to be sized before. It is resized in the function

**Vect<T\_> getRow ( size\_t *i* ) const**

Get i-th row vector.

Parameters

<b>in</b>	<i>i</i>	Index of row to extract
-----------	----------	-------------------------

Returns

[Vect](#) instance where the row is stored

Remarks

Vector *v* does not need to be sized before. It is resized in the function

**void setRow ( size\_t *i*, const Vect< T\_ > & *v* )**

Copy a given vector to a prescribed row in the matrix.

Parameters

<b>in</b>	<i>i</i>	row index to be assigned
<b>in</b>	<i>v</i>	<a href="#">Vect</a> instance to copy

**void setColumn ( size\_t *j*, const Vect< T\_ > & *v* )**

Copy a given vector to a prescribed column in the matrix.

Parameters

<b>in</b>	<i>j</i>	column index to be assigned
<b>in</b>	<i>v</i>	<a href="#">Vect</a> instance to copy

**void setDiag ( const T\_ & *a* )**

Set matrix as diagonal and assign its diagonal entries as a constant.

Parameters

<b>in</b>	<i>a</i>	Value to assign to all diagonal entries
-----------	----------	---

**void setDiag ( const vector< T\_ > & *d* )**

Set matrix as diagonal and assign its diagonal entries.

Parameters

<b>in</b>	<i>d</i>	Vector entries to assign to matrix diagonal entries
-----------	----------	---

**void add ( size\_t *i*, size\_t *j*, const T\_ & *val* )** [virtual]

Add constant to an entry of the matrix.

Parameters

<b>in</b>	<i>i</i>	row index
<b>in</b>	<i>j</i>	column index

<b>in</b>	<i>val</i>	value to add to a(i,j)
-----------	------------	------------------------

Implements [Matrix< T\\_ >](#).

**T\_ operator() ( size\_t i, size\_t j ) const** [virtual]

Operator () (Constant version).

Parameters

<b>in</b>	<i>i</i>	Row index
<b>in</b>	<i>j</i>	Column index

Implements [Matrix< T\\_ >](#).

**T\_& operator() ( size\_t i, size\_t j )** [virtual]

Operator () (Non constant version).

Parameters

<b>in</b>	<i>i</i>	Row index
<b>in</b>	<i>j</i>	Column index

Warning

To modify a value of an entry of the matrix it is safer not to modify both lower and upper triangles. Otherwise, wrong values will be assigned. If not sure, use the member functions set or add.

Implements [Matrix< T\\_ >](#).

**DSMatrix& operator+=( const T\_ & x )**

Operator +=.

Add constant value x to all matrix entries.

**DSMatrix& operator-=( const T\_ & x )**

Operator -=.

Subtract constant value x from to all matrix entries.

**int setLDLt ( )**

Factorize matrix (LDL<sup>T</sup>)

Returns

- 0, if factorization was normally performed,
- n, if the n-th pivot is null.

**void MultAdd ( T\_ a, const Vect< T\_ > & x, Vect< T\_ > & y ) const** [virtual]

Multiply matrix by vector a\*x and add to y.

Parameters

in	$a$	Constant to multiply by matrix
in	$x$	Vector to multiply by matrix
in,out	$y$	Vector to add to the result. $y$ contains on output the result.

Implements [Matrix< T\\_ >](#).

**void TMult ( const Vect< T\_ > &  $x$ , Vect< T\_ > &  $y$  ) const** [virtual]

Multiply transpose of matrix by vector  $x$  and add result in  $y$ .

Parameters

in	$x$	Vector to add to $y$
in,out	$y$	on input, vector to add to. On output, result.

Implements [Matrix< T\\_ >](#).

**void Apxy ( T\_  $a$ , const DSMatrix< T\_ > &  $m$  )**

Add to matrix the product of a matrix by a scalar.

Parameters

in	$a$	Scalar to premultiply
in	$m$	Matrix by which $a$ is multiplied. The result is added to current instance

**void Apxy ( T\_  $a$ , const Matrix< T\_ > \*  $m$  )** [virtual]

Add to matrix the product of a matrix by a scalar.

Parameters

in	$a$	Scalar to premultiply
in	$m$	Matrix by which $a$ is multiplied. The result is added to current instance

Implements [Matrix< T\\_ >](#).

**int solve ( Vect< T\_ > &  $b$ , bool  $fact = true$  )** [virtual]

Solve linear system.

The matrix is factorized using the LDLt (Crout) decomposition. If this one is already factorized, no further factorization is performed. If the matrix has been modified the user has to refactorize it using the function setLDLt.

Parameters

in,out	$b$	<a href="#">Vect</a> instance that contains right-hand side on input and solution on output.
in	$fact$	Set true if matrix is to be factorized (Default value), false if not

Returns

- 0 if solution was normally performed,
- $n$  if the  $n$ -th pivot is null.

Implements [Matrix< T\\_ >](#).

```
int solve ( const Vect< T_ > & b, Vect< T_ > & x, bool fact = true ) [virtual]
```

Solve linear system.

The matrix is factorized using the LDLt (Crout) decomposition. If this one is already factorized, no further factorization is performed. If the matrix has been modified the user has to refactorize it using the function setLDLt.

Parameters

in	<i>b</i>	<a href="#">Vect</a> instance that contains right-hand side.
out	<i>x</i>	<a href="#">Vect</a> instance that contains solution
in	<i>fact</i>	Set true if matrix is to be factorized (Default value), false if not

Returns

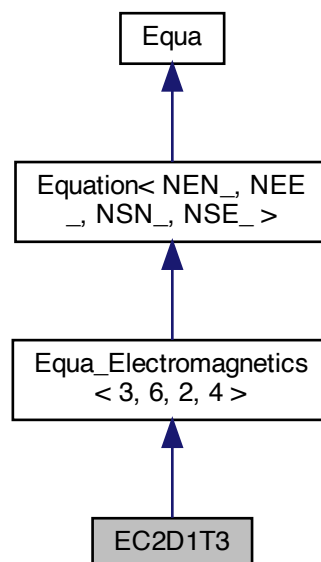

- 0 if solution was normally performed,
- *n* if the *n*-th pivot is null.

Implements [Matrix< T\\_ >](#).

### 7.16.1 Detailed Description

Eddy current problems in 2-D domains using solenoidal approximation.

Builds finite element arrays for time harmonic eddy current problems in 2-D domains with solenoidal configurations (Magnetic field has only one nonzero component). Magnetic field is constant in the vacuum, and then zero in the outer vacuum.

Uses 3-Node triangles.

The unknown is the time-harmonic magnetic induction (complex valued) but stored in 2-degree of freedom real-valued vector. Therefore, mesh must be defined with 2 degrees of freedom per node

### 7.16.2 Constructor & Destructor Documentation

**EC2D1T3 ( [Mesh](#) & *ms* )**

Constructor using mesh.

Parameters

<a href="#">in</a>	<i>ms</i>	<a href="#">Mesh</a> instance
--------------------	-----------	-------------------------------

**EC2D1T3 ( [Mesh](#) & *ms*, [Vect](#)< [real.t](#) > & *u* )**

Constructor using mesh and solution vector.

Parameters

<a href="#">in</a>	<i>ms</i>	<a href="#">Mesh</a> instance
<a href="#">in,out</a>	<i>u</i>	Reference to solution vector instance

### 7.16.3 Member Function Documentation

**void setData ( [real.t omega](#), [real.t volt](#) )**

Define data for equation.

Parameters

in	<i>omega</i>	Angular frequency
in	<i>volt</i>	Voltage

**void build ( )**

Build the linear system of equations.

Before using this function, one must have properly selected appropriate options for:

- The choice of a steady state or transient analysis. By default, the analysis is stationary
- In the case of transient analysis, the choice of a time integration scheme and a lumped or consistent capacity matrix. If transient analysis is chosen, the lumped capacity matrix option is chosen by default, and the implicit Euler scheme is used by default for time integration.

**void Magnetic ( real.t coef = 1. )**

Add magnetic contribution to matrix.

Parameters

in	<i>coef</i>	Coefficient to multiply by [Default: 1]
----	-------------	---

**void Electric ( real.t coef = 1. )**

Add electric contribution to matrix.

Parameters

in	<i>coef</i>	Coefficient to multiply by [Default: 1]
----	-------------	---

**void IntegND ( const Vect< real.t > & h, real.t & vr, real.t & vi )**

Compute integral of normal derivative on edge.

Parameters

in	<i>h</i>	<a href="#">Vect</a> instance containing magnetic field at nodes
in	<i>vr</i>	Real part of the integral
in	<i>vi</i>	Imaginary part of the integral

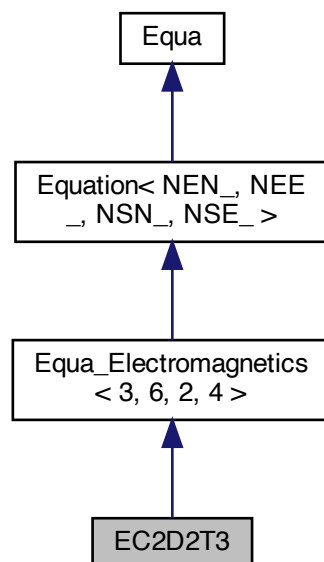

Note

This member function is to be called within each element, it detects boundary sides as the ones with nonzero code

*Operator ().*

### 7.18.1 Detailed Description

To describe an edge.

Defines an edge of a 3-D finite element mesh. The edges are given in particular by a list of nodes. Each node can be accessed by the member function `getPtrNode`.

Author

Rachid Touzani

Copyright

GNU Lesser Public License

### 7.18.2 Constructor & Destructor Documentation

**Edge ( )**

Default Constructor.

Initializes data to zero

**Edge ( *size\_t label* )**

Constructor with label.

Define an edge by giving its `label`

### 7.18.3 Member Function Documentation

**void DOF ( *size\_t i*, *size\_t dof* )**

Define label of DOF.

Parameters

<i>in</i>	<i>i</i>	DOF index
<i>in</i>	<i>dof</i>	Its label

**void setDOF ( *size\_t &first\_dof*, *size\_t nb\_dof* )**

Define number of DOF.

Parameters

<i>in,out</i>	<i>first_dof</i>	Label of the first DOF in input that is actualized
<i>in</i>	<i>nb_dof</i>	Number of DOF

**void setCode ( *size\_t dof*, *int code* )**

Assign code `code` to DOF number `dof`.

Parameters

<i>in</i>	<i>dof</i>	index of dof for assignment.
<i>in</i>	<i>code</i>	Value of code to assign.

**int getCode ( *size\_t dof = 1* ) const**

Return code for a given DOF of node.

Default value is 1

**Node\* operator() ( size\_t i ) const**

Operator ().

Return pointer to node of local label i.

**size\_t getNodeLabel ( size\_t i ) const**

Return node label.

Parameters

in	i	Local label of node for which global label is returned
----	---	--

**int isOnBoundary ( ) const**

Say if current edge is a boundary edge or not.

Note this information is available only if boundary edges were determined. See class [Mesh](#)

**Node\* operator() ( size\_t i )**

Operator ().

Returns pointer to node of local label i

## 7.19 EdgeList Class Reference

Class to construct a list of edges having some common properties.

### Public Member Functions

- [EdgeList](#) ([Mesh](#) &ms)  
*Constructor using a [Mesh](#) instance.*
- [~EdgeList](#) ()  
*Destructor.*
- void [selectCode](#) (int code, int dof=1)  
*Select edges having a given code for a given degree of freedom.*
- void [unselectCode](#) (int code, int dof=1)  
*Unselect edges having a given code for a given degree of freedom.*
- size\_t [getNbEdges](#) () const  
*Return number of selected edges.*
- void [top](#) ()  
*Reset list of edges at its top position (Non constant version)*
- void [top](#) () const  
*Reset list of edges at its top position (Constant version)*
- [Edge](#) \* [get](#) ()  
*Return pointer to current edge and move to next one (Non constant version)*
- [Edge](#) \* [get](#) () const  
*Return pointer to current edge and move to next one (Constant version)*

### 7.19.1 Detailed Description

Class to construct a list of edges having some common properties.

This class enables choosing multiple selection criteria by using function `select...`. However, the intersection of these properties must be empty.

Author

Rachid Touzani

Copyright

GNU Lesser Public License

### 7.19.2 Member Function Documentation

**void selectCode ( int code, int dof = 1 )**

Select edges having a given code for a given degree of freedom.

Parameters

in	code	Code that edges share
in	dof	Degree of Freedom label [Default: 1]

**void unselectCode ( int code, int dof = 1 )**

Unselect edges having a given code for a given degree of freedom.

Parameters

in	code	Code of edges to exclude
in	dof	Degree of Freedom label [Default: 1]

## 7.20 EigenProblemSolver Class Reference

Class to find eigenvalues and corresponding eigenvectors of a given matrix in a generalized eigenproblem, *i.e.* Find scalars  $\lambda$  and non-null vectors  $\mathbf{v}$  such that  $[\mathbf{K}]\{\mathbf{v}\} = \lambda[\mathbf{M}]\{\mathbf{v}\}$  where  $[\mathbf{K}]$  and  $[\mathbf{M}]$  are symmetric matrices. The eigenproblem can be originated from a PDE. For this, we will refer to the matrices  $\mathbf{K}$  and  $\mathbf{M}$  as *Stiffness* and *Mass* matrices respectively.

### Public Member Functions

### 7.20.2 Constructor & Destructor Documentation

**EigenProblemSolver ( DSMatrix< real.t > & K, int  $n = 0$  )**

Constructor for a dense symmetric matrix that computes the eigenvalues.

This constructor solves in place the eigenvalues problem and stores them in a vector (No need to use the function runSubSpace). The eigenvectors can be obtained by calling the member function getEigenVector.

Parameters

in	$K$	<a href="#">Matrix</a> for which eigenmodes are sought.
in	$n$	Number of eigenvalues to extract. By default all eigenvalues are computed.

**EigenProblemSolver ( SkSMatrix< real.t > & K, SkSMatrix< real.t > & M, int  $n = 0$  )**

Constructor for Symmetric Skyline Matrices.

Parameters

in	$K$	"Stiffness" matrix
in	$M$	"Mass" matrix
in	$n$	Number of eigenvalues to extract. By default all eigenvalues are computed.

Note

The generalized eigenvalue problem is defined by  $Kx = \lambda Mx$ , where  $K$  and  $M$  are referred to as stiffness and mass matrix.

**EigenProblemSolver ( SkSMatrix< real.t > & K, Vect< real.t > & M, int  $n = 0$  )**

Constructor for Symmetric Skyline Matrices.

Parameters

in	$K$	"Stiffness" matrix
in	$M$	Diagonal "Mass" matrix stored as a <a href="#">Vect</a> instance
in	$n$	Number of eigenvalues to extract. By default all eigenvalues are computed.

Note

The generalized eigenvalue problem is defined by  $Kx = \lambda Mx$ , where  $K$  and  $M$  are referred to as stiffness and mass matrix.

**EigenProblemSolver ( DSMatrix< real.t > & A, Vect< real.t > & ev, int  $n = 0$  )**

Constructor for a dense matrix that compute the eigenvalues.

This constructor solves in place the eigenvalues problem and stores them in a vector (No need to use the function runSubSpace). The eigenvectors can be obtained by calling the member function getEigenVector.

Parameters

in	$A$	<a href="#">Matrix</a> for which eigenmodes are sought.
in	$ev$	Vector containing all computed eigenvalues sorted increasingly.
in	$n$	Number of eigenvalues to extract. By default all eigenvalues are computed.

Remarks

The vector  $ev$  does not need to be sized before.

**EigenProblemSolver ( *Equa* & *eq*, bool *lumped* = *true* )**

Constructor using partial differential equation.

The used equation class must have been constructed using the [Mesh](#) instance

Parameters

in	<i>eq</i>	Reference to equation instance
in	<i>lumped</i>	Mass matrix is lumped ( <i>true</i> ) or not ( <i>false</i> ) [Default: <i>true</i> ]

### 7.20.3 Member Function Documentation

**void setMatrix ( SkSMatrix< real\_t > & *K*, SkSMatrix< real\_t > & *M* )**

Set matrix instances (Symmetric matrices).

This function is to be used when the default constructor is applied. Case where the mass matrix is consistent.

Parameters

in	$K$	Stiffness matrix instance
in	$M$	Mass matrix instance

**void setMatrix ( SkSMatrix< real\_t > & *K*, Vect< real\_t > & *M* )**

Set matrix instances (Symmetric matrices).

This function is to be used when the default constructor is applied. Case where the mass matrix is (lumped) diagonal and stored in a vector.

Parameters

in	$K$	Stiffness matrix instance
in	$M$	Mass matrix instance where diagonal terms are stored as a vector.

**void setMatrix ( DSMatrix< real\_t > & *K* )**

Set matrix instance (Symmetric matrix).

This function is to be used when the default constructor is applied. Case of a standard (not generalized) eigen problem is to be solved

Parameters

in	$K$	Stiffness matrix instance
----	-----	---------------------------

**void setPDE ( *Equa* & *eq*, bool *lumped* = *true* )**

Define partial differential equation to solve.

The used equation class must have been constructed using the [Mesh](#) instance

Parameters

<code>in</code>	<code>eq</code>	Reference to equation instance
<code>in</code>	<code>lumped</code>	Mass matrix is lumped ( <i>true</i> ) or not ( <i>false</i> ) [Default: <code>true</code> ]

**int run ( int *nb* = 0 )**

Run the eigenproblem solver.

Parameters

<code>in</code>	<code>nb</code>	Number of eigenvalues to be computed. By default, all eigenvalues are computed.
-----------------	-----------------	---

**void Assembly ( const Element & *el*, real\_t \* *eK*, real\_t \* *eM* )**

Assemble element arrays into global matrices.

This member function is to be called from finite element equation classes

Parameters

<code>in</code>	<code>el</code>	Reference to <a href="#">Element</a> class
<code>in</code>	<code>eK</code>	Pointer to element stiffness (or assimilated) matrix
<code>in</code>	<code>eM</code>	Pointer to element mass (or assimilated) matrix

**void SAssembly ( const Side & *sd*, real\_t \* *sK* )**

Assemble side arrays into global matrix and right-hand side.

This member function is to be called from finite element equation classes

Parameters

<code>in</code>	<code>sd</code>	Reference to <a href="#">Side</a> class
<code>in</code>	<code>sK</code>	Pointer to side stiffness

**int runSubSpace ( size\_t *nb\_eigv*, size\_t *ss\_dim* = 0 )**

Run the subspace iteration solver.

This function runs the Bathe subspace iteration method.

Parameters

<code>in</code>	<code>nb_eigv</code>	Number of eigenvalues to be extracted
<code>in</code>	<code>ss_dim</code>	Subspace dimension. Must be at least equal to the number eigenvalues to seek. [Default: <code>nb_eigv</code> ]

Returns

1: Normal execution. Convergence has been achieved. 2: Convergence for eigenvalues has not been attained.

**void setSubspaceDimension ( int *dim* )**

Define the subspace dimension.

Parameters

<b>in</b>	<i>dim</i>	Subspace dimension. Must be larger or equal to the number of wanted eigenvalues. By default this value will be set to the number of wanted eigenvalues
-----------	------------	--

**void setTolerance ( real\_t *eps* )**

set tolerance value

Parameters

<b>in</b>	<i>eps</i>	Convergence tolerance for eigenvalues [Default: 1.e-8]
-----------	------------	--

**int checkSturm ( int & *nb\_found*, int & *nb\_lost* )**

Check how many eigenvalues have been found using Sturm sequence method.

Parameters

<b>out</b>	<i>nb_found</i>	number of eigenvalues actually found
<b>out</b>	<i>nb_lost</i>	number of eigenvalues missing

Returns

- 0, Successful completion of subroutine.
- 1, No convergent eigenvalues found.

**void getEigenVector ( int *n*, Vect< real\_t > & *v* ) const**

Return the n-th eigenvector.

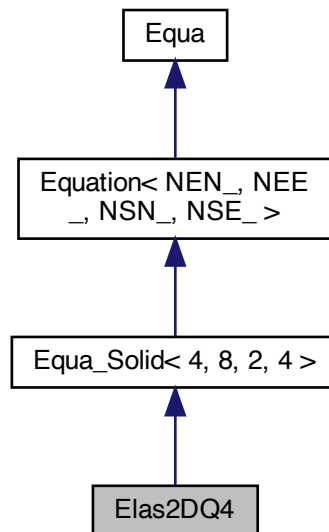

Parameters

<b>in</b>	<i>n</i>	Label of eigenvector (They are stored in ascending order of eigenvalues)
<b>in,out</b>	<i>v</i>	<a href="#">Vect</a> instance where the eigenvector is stored.

### 7.21.1 Detailed Description

To build element equations for 2-D linearized elasticity using 4-node quadrilaterals.

This class enables building finite element arrays for linearized isotropic elasticity problem in 2-D domains using 4-Node quadrilaterals.

Unilateral contact is handled using a penalty function. Note that members calculating element arrays have as an argument a real `coef` that is multiplied by the contribution of the current element. This makes possible testing different algorithms.

### 7.21.2 Constructor & Destructor Documentation

#### Elas2DQ4 ( )

Default Constructor.

Constructs an empty equation.

#### Elas2DQ4 ( Mesh & *ms* )

Constructor using [Mesh](#) instance.

Parameters

<code>in</code>	<code>ms</code>	Reference to <a href="#">Mesh</a> instance
-----------------	-----------------	--

#### Elas2DQ4 ( Mesh & *ms*, Vect< real.t > & *u* )

Constructor using [Mesh](#) instance and solution vector.

Parameters

<code>in</code>	<code>ms</code>	Reference to <a href="#">Mesh</a> instance
<code>in,out</code>	<code>u</code>	Solution vector

### 7.21.3 Member Function Documentation

#### void PlaneStrain ( real.t *E*, real.t *nu* )

Set plane strain hypothesis by giving values of Young's modulus and Poisson ratio.

Parameters

<code>in</code>	<code>E</code>	Young's modulus
<code>in</code>	<code>nu</code>	Poisson ratio

#### void PlaneStress ( real.t *E*, real.t *nu* )

Set plane stress hypothesis by giving values of Young's modulus and Poisson ratio.

Parameters

<code>in</code>	<code>E</code>	Young's modulus
<code>in</code>	<code>nu</code>	Poisson ratio

#### void BodyRHS ( const Vect< real.t > & *f* )

Add body right-hand side term to right hand side.

Parameters

<i>in</i>	<i>f</i>	Vector containing source at nodes (DOF by DOF).
-----------	----------	---

**void BoundaryRHS ( const Vect< real\_t > &f )**

Add boundary right-hand side term to right hand side.

Parameters

<i>in</i>	<i>f</i>	Vector containing source at nodes (DOF by DOF).
-----------	----------	---

**void Strain ( Vect< real\_t > &eps )**

Calculate strains at element barycenters.

Parameters

<i>out</i>	<i>eps</i>	Vector containing strains in elements
------------	------------	---------------------------------------

Remarks

The instance of [Elas2DQ4](#) must have been constructed using the constructor with [Mesh](#) instance and solution vector

**void Stress ( Vect< real\_t > &st, Vect< real\_t > &vm )**

Calculate principal stresses and Von-Mises stress at element barycenter.

Parameters

<i>out</i>	<i>st</i>	Vector containing principal stresses in elements
<i>out</i>	<i>vm</i>	Vector containing Von-Mises stresses in elements

Remarks

The instance of [Elas2DQ4](#) must have been constructed using the constructor with [Mesh](#) instance and solution vector

**void Stress ( Vect< real\_t > &sigma, Vect< real\_t > &s, Vect< real\_t > &st )**

Calculate principal stresses and Von-Mises stress at element barycenter.

Parameters

<i>out</i>	<i>sigma</i>	Vector containing principal stresses in elements
<i>out</i>	<i>s</i>	Vector containing principal stresses in elements
<i>out</i>	<i>st</i>	Value of Von-Mises stress in elements

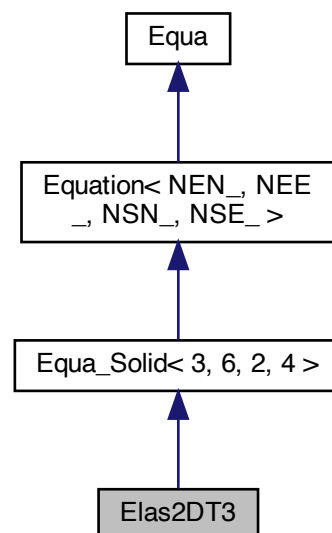

Remarks

The instance of [Elas2DQ4](#) must have been constructed using the constructor with [Mesh](#) instance and solution vector

### 7.22.1 Detailed Description

To build element equations for 2-D linearized elasticity using 3-node triangles.

This class enables building finite element arrays for linearized isotropic elasticity problem in 2-D domains using 3-Node triangles.

Unilateral contact is handled using a penalty function. Note that members calculating element arrays have as an argument a real `coef` that is multiplied by the contribution of the current element. This makes possible testing different algorithms.

### 7.22.2 Constructor & Destructor Documentation

**Elas2DT3** ( )

Default Constructor.

Constructs an empty equation.

**Elas2DT3** ( **Mesh** & *ms* )

Constructor using **Mesh** data.

Parameters

<b>in</b>	<i>ms</i>	<a href="#">Mesh</a> instance
-----------	-----------	-------------------------------

**Elas2DT3 ( [Mesh](#) & *ms*, Vect< real.t > & *u* )**

Constructor using [Mesh](#) data and solution vector.

Parameters

<b>in</b>	<i>ms</i>	<a href="#">Mesh</a> instance
<b>in,out</b>	<i>u</i>	Reference to solution vector

### 7.22.3 Member Function Documentation

**void Media ( real.t *E*, real.t *nu*, real.t *rho* )**

Set media properties.

Useful to override material properties deduced from mesh file.

**void LMass ( real.t *coef* = 1. )** [virtual]

Add element lumped mass contribution to element matrix after multiplication by *coef*

Parameters

<b>in</b>	<i>coef</i>	Coefficient to multiply by added term [Default: 1].
-----------	-------------	---

Reimplemented from [Equa.Solid< 3, 6, 2, 4 >](#).

**void Mass ( real.t *coef* = 1. )** [virtual]

Add element consistent mass contribution to element matrix after multiplication by *coef*

Parameters

<b>in</b>	<i>coef</i>	Coefficient to multiply by added term [Default: 1].
-----------	-------------	---

Reimplemented from [Equa.Solid< 3, 6, 2, 4 >](#).

**void Deviator ( real.t *coef* = 1. )** [virtual]

Add element deviatoric matrix to element matrix after multiplication by *coef*

Parameters

<b>in</b>	<i>coef</i>	Coefficient to multiply by added term [Default: 1].
-----------	-------------	---

Reimplemented from [Equa.Solid< 3, 6, 2, 4 >](#).

**void Dilatation ( real.t *coef* = 1. )** [virtual]

Add element dilatational contribution to element matrix after multiplication by *coef*

Parameters

<b>in</b>	<i>coef</i>	Coefficient to multiply by added term [Default: 1].
-----------	-------------	---

Reimplemented from [Equa.Solid< 3, 6, 2, 4 >](#).

**void BodyRHS ( const Vect< real.t > & *f* )**

Add body right-hand side term to right hand side.

Parameters

in	<i>f</i>	Vector containing source at nodes (DOF by DOF)
----	----------	--

**void BoundaryRHS ( const Vect< real\_t > &f )**

Add boundary right-hand side term to right hand side.

Parameters

in	<i>f</i>	Vect instance that contains constant traction to impose to side.
----	----------	--

**int Contact ( real\_t coef = 1.e07 )**

Penalty Signorini contact side contribution to matrix and right-hand side.

Parameters

in	<i>coef</i>	Penalty value by which the added term is multiplied [Default↵ : 1.e07]
----	-------------	--

Returns

= 0 if no contact is achieved on this side, 1 otherwise

**void Reaction ( Vect< real\_t > &r )**

Calculate reactions.

This function can be invoked in postprocessing

Parameters

in	<i>r</i>	Reaction on the side
----	----------	----------------------

**void ContactPressure ( const Vect< real\_t > &f, real\_t penal, Point< real\_t > &p )**

Calculate contact pressure.

This function can be invoked in postprocessing

Parameters

in	<i>f</i>	Penalty parameter that was used to impose contact condition
in	<i>penal</i>	
out	<i>p</i>	Contact pressure

**void Strain ( Vect< real\_t > &eps )**

Calculate strains in element.

This function can be invoked in postprocessing.

Parameters

out	<i>eps</i>	vector of strains in elements
-----	------------	-------------------------------

**void Stress ( Vect< real\_t > &s, Vect< real\_t > &vm )**

Calculate principal stresses and Von-Mises stress in element.

Parameters

out	<i>s</i>	vector of principal stresses in elements
out	<i>vm</i>	Von-Mises stresses in elements This function can be invoked in postprocessing.

**void Periodic ( real\_t coef = 1.e20 )**

Add contribution of periodic boundary condition (by a penalty technique).

Boundary nodes where periodic boundary conditions are to be imposed must have codes equal to PERIODIC\_A on one side and PERIODIC\_B on the opposite side.

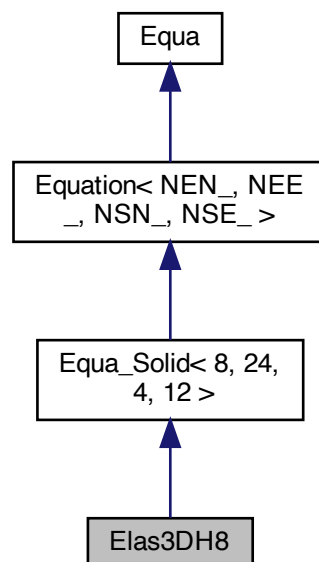

Parameters

in	<i>coef</i>	Value of penalty parameter [Default: 1.e20]
----	-------------	---

### 7.25.1 Detailed Description

To store and treat finite element geometric information.

Class `Element` enables defining an element of a finite element mesh. The element is given in particular by its shape and a list of nodes. Each node can be accessed by the member function `getPtrNode`. Moreover, class `Mesh` can generate for each element its list of sides. The string that defines the element shape must be chosen according to the following list:

Shape	Shape name	Dimension	Min. number of nodes
Line	line 2 2	<code>Triangle</code>	tria 2 3
Quadrilateral	quad 2 4	Tetrahedron	tetra 3 4
		Pentahedron	penta 3 6
		Hexahedron	hexa 3 8

Remarks

Once a `Mesh` instance is constructed, one has access for each `Element` of the mesh to pointers to element sides provided the member function `getAllSides` of `Mesh` has been invoked. With this, an element can be tested to see if it is on the boundary, i.e. if it has at least one side on the boundary

## 7.25.2 Constructor & Destructor Documentation

**Element ( `size_t label`, `const string & shape` )**

Constructor initializing label, shape of element.

Parameters

<code>in</code>	<i>label</i>	Label to assign to element.
<code>in</code>	<i>shape</i>	Shape of element (See class description).

**Element ( `size_t label`, `int shape` )**

Constructor initializing label, shape of element.

Parameters

<code>in</code>	<i>label</i>	Label to assign to element.
<code>in</code>	<i>shape</i>	Shape of element (See enum <code>ElementShape</code> in <a href="#">Mesh</a> )

**Element ( `size_t label`, `const string & shape`, `int c` )**

Constructor initializing label, shape and code of element.

Parameters

<code>in</code>	<i>label</i>	Label to assign to element.
<code>in</code>	<i>shape</i>	Shape of element (See class description).
<code>in</code>	<i>c</i>	Code to assign to element (useful for media properties).

**Element ( `size_t label`, `int shape`, `int c` )**

Constructor initializing label, shape and code of element.

Parameters

<code>in</code>	<i>label</i>	Label to assign to element.
<code>in</code>	<i>shape</i>	Shape of element (See enum <code>ElementShape</code> in <a href="#">Mesh</a> ).
<code>in</code>	<i>c</i>	Code to assign to element (useful for media properties).

## 7.25.3 Member Function Documentation

**void setLabel ( `size_t i` )**

Define label of element.

Parameters

<b>in</b>	<i>i</i>	Label to assign to element
-----------	----------	----------------------------

**void setCode ( int *c* )**

Define code of element.

Parameters

<b>in</b>	<i>c</i>	Code to assign to element.
-----------	----------	----------------------------

**void Add ( Node \* *node* )**

Insert a node at end of list of nodes of element.

Parameters

<b>in</b>	<i>node</i>	Pointer to <a href="#">Node</a> instance.
-----------	-------------	---

**void Add ( Node \* *node*, int *n* )**

Insert a node and set its local node number.

Parameters

	<i>node</i>	[in] Pointer to <a href="#">Node</a> instance
<b>in</b>	<i>n</i>	<a href="#">Element</a> node number to assign

**void Replace ( size.t *label*, Node \* *node* )**

Replace a node at a given local label.

Parameters

<b>in</b>	<i>label</i>	<a href="#">Node</a> to replace.
<b>in</b>	<i>node</i>	Pointer to <a href="#">Node</a> instance to copy to current instance.

**void Replace ( size.t *label*, Side \* *side* )**

Replace a side at a given local label.

Parameters

<b>in</b>	<i>label</i>	<a href="#">Side</a> to replace.
<b>in</b>	<i>side</i>	Pointer to <a href="#">Side</a> instance to copy to current instance.

**void Add ( Side \* *sd* )**

Assign [Side](#) to [Element](#).

Parameters

<b>in</b>	<i>sd</i>	Pointer to <a href="#">Side</a> instance.
-----------	-----------	---

**void Add ( Side \* *sd*, int *k* )**

Assign [Side](#) to [Element](#) with assigned local label.

Parameters

<code>in</code>	<code>sd</code>	Pointer to <a href="#">Side</a> instance.
<code>in</code>	<code>k</code>	Local label.

**void Add ( Element \* *el* )**

Add a neighbor element.

Parameters

<code>in</code>	<code>el</code>	Pointer to <a href="#">Element</a> instance
-----------------	-----------------	---

**void set ( Element \* *el*, int *n* )**

Add a neighbor element and set its label.

Parameters

<code>in</code>	<code>el</code>	Pointer to <a href="#">Element</a> instance
<code>in</code>	<code>n</code>	Neighbor element number to assign

**void setDOF ( size\_t *i*, size\_t *dof* )**

Define label of DOF.

Parameters

<code>in</code>	<code>i</code>	Index of DOF.
<code>in</code>	<code>dof</code>	Label of DOF to assign.

**void setCode ( size\_t *dof*, int *code* )**

Assign code to a DOF.

Parameters

<code>in</code>	<code>dof</code>	Index of dof for assignment.
<code>in</code>	<code>code</code>	Code to assign.

**Node\* operator() ( size\_t *i* ) const**

Operator ().

Return pointer to node of local label *i*.

**int Contains ( const Node \* *nd* ) const**

Say if element contains given node.

This function tests if the element contains a node with the same pointer at the sought one

Parameters

<code>in</code>	<code>nd</code>	Pointer to <a href="#">Node</a> instance
-----------------	-----------------	--

Returns

Local node label in element. If 0, the element does not contain this node

**int Contains ( const Node & *nd* ) const**

Say if element contains given node.

This function tests if the element contains a node with the same label at the sought one

Parameters

<i>in</i>	<i>nd</i>	Reference to <a href="#">Node</a> instance
-----------	-----------	--

Returns

Local node label in element. If 0, the element does not contain this node

**int Contains ( const Side \* *sd* ) const**

Say if element contains given side.

This function tests if the element contains a side with the same pointer at the sought one

Parameters

<i>in</i>	<i>sd</i>	Pointer to <a href="#">Side</a> instance
-----------	-----------	--

Returns

Local side label in element. If 0, the element does not contain this side

**int Contains ( const Side & *sd* ) const**

Say if element contains given side.

This function tests if the element contains a side with the same label at the sought one

Parameters

<i>in</i>	<i>sd</i>	Reference to <a href="#">Side</a> instance
-----------	-----------	--

Returns

Local side label in element. If 0, the element does not contain this side

**Element\* getNeighborElement ( size\_t *i* ) const**

Return pointer to element Neighboring element.

Parameters

<i>in</i>	<i>i</i>	Index of element to look for.
-----------	----------	-------------------------------

Note

This method returns valid information only if the [Mesh](#) member function [Mesh::getElement↔NeighborElements\(\)](#) has been called before.

**size\_t getNbNeigElements ( ) const**

Return number of neighboring elements.

Note

This method returns valid information only if the [Mesh](#) member function [Mesh::getElement↔NeighborElements\(\)](#) has been called before.

**real\_t getMeasure ( ) const**

Return measure of element.

This member function returns length, area or volume of element. In case of quadrilaterals and hexahedrals it returns determinant of Jacobian of mapping between reference and actual element

**Point<real\_t> getUnitNormal ( size\_t i ) const**

Return outward unit normal to i-th side of element.

Sides are ordered [node\_1,node\_2], [node\_2,node\_3], ...

**bool isOnBoundary ( ) const**

Say if current element is a boundary element or not.

Note

this information is available only if boundary elements were determined i.e. if member function [Mesh::getBoundarySides](#) or [Mesh::getAllSides](#) has been invoked before.

**Node\* operator() ( size\_t i )**

Operator ().

Return pointer to node of local label i.

**int setSide ( size\_t n, size\_t \* nd )**

Initialize information on element sides.

This function is to be used to initialize loops over sides.

Parameters

in	<i>n</i>	Label of side.
in	<i>nd</i>	Array of pointers to nodes of the side (nd[0], nd[1], ... point to first, second nodes, ...

**void setChild ( Element \* el )**

Assign element as child of current one and assign current element as father This function is principally used when refining is invoked (e.g. for mesh adaption)

Parameters

in	<i>el</i>	Pointer to element to assign
----	-----------	------------------------------

**size\_t IsIn ( const Node \* nd )**

Check if a given node belongs to current element.

Parameters

in	<i>nd</i>	Pointer to node to locate
----	-----------	---------------------------

Returns

local label of node if this one is found, 0 otherwise

## 7.26 ElementList Class Reference

Class to construct a list of elements having some common properties.

### Public Member Functions

- [ElementList](#) ([Mesh](#) &ms)  
*Constructor using a [Mesh](#) instance.*
- [~ElementList](#) ()  
*Destructor.*
- void [selectCode](#) (int code)  
*Select elements having a given code.*
- void [unselectCode](#) (int code)  
*Unselect elements having a given code.*
- void [selectLevel](#) (int level)  
*Select elements having a given level.*
- size\_t [getNbElements](#) () const  
*Return number of selected elements.*
- void [top](#) ()  
*Reset list of elements at its top position (Non constant version)*
- void [top](#) () const  
*Reset list of elements at its top position (Constant version)*
- [Element](#) \* [get](#) ()  
*Return pointer to current element and move to next one (Non constant version)*
- [Element](#) \* [get](#) () const  
*Return pointer to current element and move to next one (Constant version)*

### 7.26.1 Detailed Description

Class to construct a list of elements having some common properties.

This class enables choosing multiple selection criteria by using function `select...`. However, the intersection of these properties must be empty.

Author

Rachid Touzani

Copyright

GNU Lesser Public License

### 7.26.2 Member Function Documentation

**void unselectCode ( int code )**

Unselect elements having a given code.

Parameters

---

<code>in</code>	<code>code</code>	Code of elements to exclude
-----------------	-------------------	-----------------------------

**void selectLevel ( int *level* )**

Select elements having a given level.

Parameters

<code>in</code>	<code>level</code>	Level of elements to select
-----------------	--------------------	-----------------------------

Elements having a given level (for mesh adaption) are selected in a list

## 7.27 Ellipse Class Reference

To store and treat an ellipsoidal figure.

Inheritance diagram for Ellipse:

Collaboration diagram for Ellipse:

### Public Member Functions

- [Ellipse \(\)](#)

*Default constructor.*

- `Ellipse (Point< real_t > c, real_t a, real_t b, int code=1)`  
*Constructor with given ellipse data.*
- `real_t getSignedDistance (const Point< real_t > &p) const`  
*Return signed distance of a given point from the current ellipse.*
- `Ellipse & operator+= (Point< real_t > a)`  
*Operator +=*
- `Ellipse & operator*= (real_t a)`  
*Operator \*=*

### 7.27.1 Detailed Description

To store and treat an ellipsoidal figure.

### 7.27.2 Constructor & Destructor Documentation

`Ellipse ( )`

Default constructor.

Constructs an ellipse with semimajor axis = 1, and semiminor axis = 1

`Ellipse ( Point< real_t > c, real_t a, real_t b, int code = 1 )`

Constructor with given ellipse data.

Parameters

in	<i>c</i>	Coordinates of center
in	<i>a</i>	Semimajor axis
in	<i>b</i>	Semiminor axis
in	<i>code</i>	Code to assign to the generated figure [Default: 1]

### 7.27.3 Member Function Documentation

`real_t getSignedDistance ( const Point< real_t > &p ) const` [virtual]

Return signed distance of a given point from the current ellipse.

The computed distance is negative if *p* lies in the ellipse, positive if it is outside, and 0 on its boundary

Parameters

in	<i>p</i>	Point<double> instance
----	----------	------------------------

Reimplemented from [Figure](#).

`Ellipse& operator+= ( Point< real_t > a )`

Operator +=

Translate ellipse by a vector *a*

Parameters

in	<i>a</i>	Vector defining the translation
----	----------	---------------------------------

`Ellipse& operator*= ( real_t a )`

Operator \*=

Scale ellipse by a factor *a*

Parameters

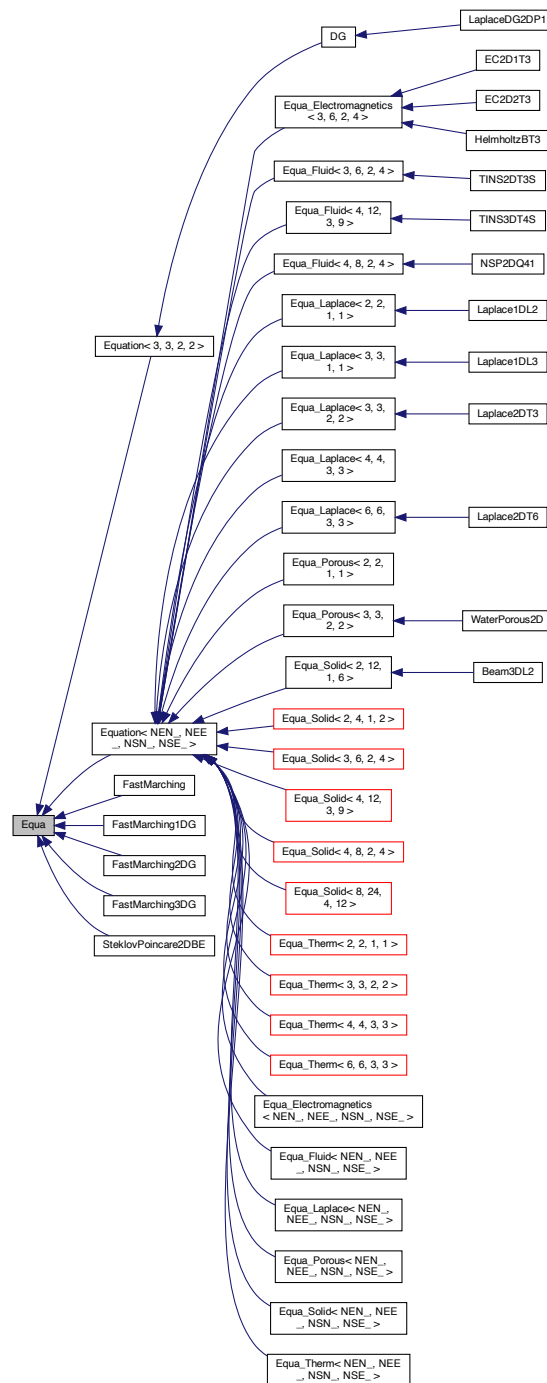

<code>in</code>	$a$	Scaling value
-----------------	-----	---------------

## 7.28 Equa Class Reference

Mother abstract class to describe equation.

Inheritance diagram for Equa:

## Public Member Functions

- [Equa](#) ()  
*Default constructor.*

- virtual `~Equa ()`  
*Destructor.*
- void `setMesh (Mesh &m)`  
*Define mesh and renumber DOFs after removing imposed ones.*
- `Mesh & getMesh () const`  
*Return reference to `Mesh` instance.*
- `LinearSolver< real_t > & getLinearSolver ()`  
*Return reference to linear solver instance.*
- `Matrix< real_t > * getMatrix () const`  
*Return pointer to matrix.*
- void `setSolver (Iteration ls, Preconditioner pc=IDENT_PREC)`  
*Choose solver for the linear system.*
- void `setLinearSolver (Iteration ls, Preconditioner pc=IDENT_PREC)`  
*Choose solver for the linear system.*
- void `setMatrixType (int t)`  
*Choose type of matrix.*
- int `solveLinearSystem (Matrix< real_t > *A, Vect< real_t > &b, Vect< real_t > &x)`  
*Solve the linear system with given matrix and right-hand side.*
- int `solveLinearSystem (Vect< real_t > &b, Vect< real_t > &x)`  
*Solve the linear system with given right-hand side.*

### 7.28.1 Detailed Description

Mother abstract class to describe equation.

Author

Copyright

GNU Lesser Public License

### 7.28.2 Member Function Documentation

**`Mesh& getMesh ( ) const`**

Return reference to `Mesh` instance.

Returns

Reference to `Mesh` instance

**`void setSolver ( Iteration ls, Preconditioner pc = IDENT_PREC )`**

Choose solver for the linear system.

## Parameters

in	ls	<p>Solver of the linear system. To choose among the enumerated values: DIRECT_SOLVER, CG_SOLVER, GMRES_SOLVER</p> <ul style="list-style-type: none"> <li>• DIRECT_SOLVER, Use a facorization solver [default]</li> <li>• CG_SOLVER, Conjugate Gradient iterative solver</li> <li>• CGS_SOLVER, Squared Conjugate Gradient iterative solver</li> <li>• BICG_SOLVER, BiConjugate Gradient iterative solver</li> <li>• BICG_STAB_SOLVER, BiConjugate Gradient Stabilized iterative solver</li> <li>• GMRES_SOLVER, GMRES iterative solver</li> <li>• QMR_SOLVER, QMR iterative solver</li> </ul>
in	pc	<p>Preconditioner to associate to the iterative solver. If the direct solver was chosen for the first argument this argument is not used. Otherwise choose among the enumerated values:</p> <ul style="list-style-type: none"> <li>• IDENT_PREC, Identity preconditioner (no preconditioning [default])</li> <li>• DIAG_PREC, Diagonal preconditioner</li> <li>• ILU_PREC, Incomplete LU factorization preconditioner</li> </ul>

**void setLinearSolver ( Iteration *ls*, Preconditioner *pc* = IDENT\_PREC )**

Choose solver for the linear system.

## Parameters

in	ls	<p>Solver of the linear system. To choose among the enumerated values: DIRECT_SOLVER, CG_SOLVER, GMRES_SOLVER</p> <ul style="list-style-type: none"> <li>• DIRECT_SOLVER, Use a facorization solver [default]</li> <li>• CG_SOLVER, Conjugate Gradient iterative solver</li> <li>• CGS_SOLVER, Squared Conjugate Gradient iterative solver</li> <li>• BICG_SOLVER, BiConjugate Gradient iterative solver</li> <li>• BICG_STAB_SOLVER, BiConjugate Gradient Stabilized iterative solver</li> <li>• GMRES_SOLVER, GMRES iterative solver</li> <li>• QMR_SOLVER, QMR iterative solver</li> </ul>
----	----	---

in	<i>pc</i>	Preconditioner to associate to the iterative solver. If the direct solver was chosen for the first argument this argument is not used. Otherwise choose among the enumerated values: <ul style="list-style-type: none"> <li>• IDENT.PREC, Identity preconditioner (no preconditioning [default])</li> <li>• DIAG.PREC, Diagonal preconditioner</li> <li>• ILU.PREC, Incomplete LU factorization preconditioner</li> </ul>
----	-----------	---

**void setMatrixType ( int *t* )**

Choose type of matrix.

Parameters

in	<i>t</i>	Type of the used matrix. To choose among the enumerated values: SKYLINE, SPARSE, DIAGONAL TRIDIAGONAL, SYMMETRIC, U↔NSYMMETRIC, IDENTITY
----	----------	--

**int solveLinearSystem ( Matrix< real.t > \**A*, Vect< real.t > &*b*, Vect< real.t > &*x* )**

Solve the linear system with given matrix and right-hand side.

Parameters

in	<i>A</i>	Pointer to matrix of the system
in	<i>b</i>	Vector containing right-hand side
in,out	<i>x</i>	Vector containing initial guess of solution on input, actual solution on output

**int solveLinearSystem ( Vect< real.t > &*b*, Vect< real.t > &*x* )**

Solve the linear system with given right-hand side.

Parameters

in	<i>b</i>	Vector containing right-hand side
in,out	<i>x</i>	Vector containing initial guess of solution on input, actual solution on output

## 7.29 Equa\_Electromagnetics< NEN\_, NEE\_, NSN\_, NSE\_ > Class Template Reference

Abstract class for Electromagnetics [Equation](#) classes.

### 7.31.2 Constructor & Destructor Documentation

**Equa\_Laplace** ( )

Default constructor.

Constructs an empty equation.

### 7.31.3 Member Function Documentation

**virtual void BodyRHS** ( const [Vect](#)< [real.t](#) > &f ) [virtual]

Add body source term to right-hand side.

Parameters

in	$f$	Vector containing the source given function at mesh nodes
----	-----	---

Reimplemented in [Laplace2DT3](#), [Laplace1DL2](#), [Laplace1DL3](#), and [Laplace2DT6](#).

**virtual void BoundaryRHS ( const Vect< real\_t > &  $h$  )** [virtual]

Add boundary source term to right-hand side.

Parameters

in	$h$	Vector containing the source given function at mesh nodes
----	-----	---

Reimplemented in [Laplace2DT3](#), [Laplace1DL2](#), [Laplace1DL3](#), and [Laplace2DT6](#).

**void build ( )**

Build global matrix and right-hand side.

The problem matrix and right-hand side are the ones used in the constructor. They are updated in this member function.

**void build ( EigenProblemSolver &  $e$  )**

Build the linear system for an eigenvalue problem.

Parameters

in	$e$	Reference to used <a href="#">EigenProblemSolver</a> instance
----	-----	---

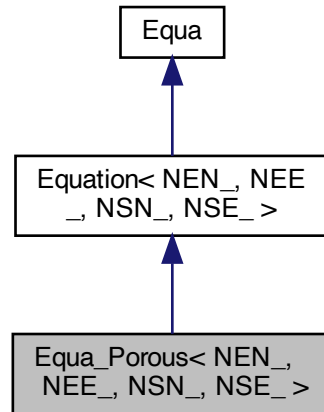

## 7.32 Equa\_Porous< NEN\_, NEE\_, NSN\_, NSE\_ > Class Template Reference

Abstract class for Porous Media Finite Element classes.

### 7.32.1 Detailed Description

**template<size\_t NEN\_, size\_t NEE\_, size\_t NSN\_, size\_t NSE\_>class OFELI::Equa\_Porous< NEN\_, NEE\_, NSN\_, NSE\_ >**

Abstract class for Porous Media Finite Element classes.  
Template Parameters

<T_>	data type (real_t, float, ...)
<NEN_>	Number of element nodes
<NEE_>	Number of element equations
<NSN_>	Number of side nodes
<NSE_>	Number of side equations

### 7.32.2 Constructor & Destructor Documentation

**Equa\_Porous ( )**

Default constructor.  
Constructs an empty equation.

### 7.32.3 Member Function Documentation

**virtual void BodyRHS ( const Vect< real\_t > & bf )** [virtual]

Add source right-hand side term to right-hand side.  
Parameters

in	bf	Vector containing source at nodes.
----	----	------------------------------------

Reimplemented in [WaterPorous2D](#).

**virtual void BoundaryRHS ( const Vect< real\_t > & sf )** [virtual]

Add boundary right-hand side term to right-hand side.  
Parameters

in	sf	Vector containing source at nodes.
----	----	------------------------------------

Reimplemented in [WaterPorous2D](#).

**void build ( )**

Build the linear system of equations.  
Before using this function, one must have properly selected appropriate options for:

- The choice of a steady state or transient analysis. By default, the analysis is stationary
- In the case of transient analysis, the choice of a time integration scheme and a lumped or consistent capacity matrix. If transient analysis is chosen, the lumped capacity matrix option is chosen by default, and the implicit Euler scheme is used by default for time integration.

### **void build ( TimeStepping & s )**

Build the linear system of equations.

Before using this function, one must have properly selected appropriate options for:

- The choice of a steady state or transient analysis. By default, the analysis is stationary
- In the case of transient analysis, the choice of a time integration scheme. If transient analysis is chosen, the implicit Euler scheme is used by default for time integration.

Parameters

<b>in</b>	<b>s</b>	Reference to used <a href="#">TimeStepping</a> instance
-----------	----------	---

### **void build ( EigenProblemSolver & e )**

Build the linear system for an eigenvalue problem.

Parameters

<b>in</b>	<b>e</b>	Reference to used <a href="#">EigenProblemSolver</a> instance
-----------	----------	---

### **int run ( )**

Run the equation.

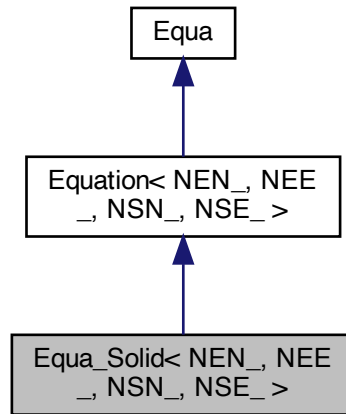

If the analysis (see function setAnalysis) is STEADY\_STATE, then the function solves the stationary equation.

If the analysis is TRANSIENT, then the function performs time stepping until the final time is reached.

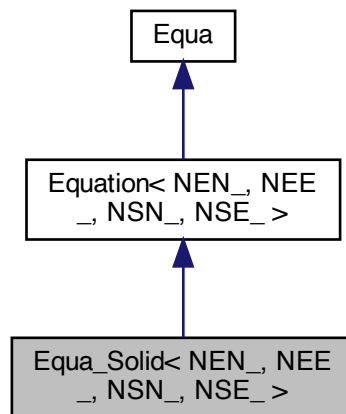

## **7.33 Equa\_Solid< NEN\_, NEE\_, NSN\_, NSE\_ > Class Template Reference**

Abstract class for Solid Mechanics Finite Element classes.

Inheritance diagram for Equa\_Solid< NEN\_, NEE\_, NSN\_, NSE\_ >:

Collaboration diagram for Equa\_Solid< NEN\_, NEE\_, NSN\_, NSE\_ >:

## Public Member Functions

*Set material properties.*

### 7.33.1 Detailed Description

**template<size.t  $NEN$ -, size.t  $NEE$ -, size.t  $NSN$ -, size.t  $NSE$ ->class OFELI::Equa.Solid<  $NEN$ -,  $NEE$ -,  $NSN$ -,  $NSE$ - >**

Abstract class for Solid Mechanics Finite Element classes.  
Template Parameters

< $NEN$ >	Number of element nodes
< $NEE$ ->	Number of element equations
< $NSN$ ->	Number of side nodes
< $NSE$ ->	Number of side equations

### 7.33.2 Constructor & Destructor Documentation

**Equa.Solid ( )**

Default constructor.

Constructs an empty equation.

### 7.33.3 Member Function Documentation

**virtual void LMass ( *real\_t coef = 1* )** [virtual]

Add lumped mass contribution to left-hand side.

Parameters

<code>in</code>	<code>coef</code>	coefficient to multiply by the matrix before adding [Default: 1]
-----------------	-------------------	--

Reimplemented in [Beam3DL2](#), [Elas2DT3](#), [Elas2DQ4](#), [Elas3DT4](#), [Bar2DL2](#), and [Elas3DH8](#).

**virtual void Mass ( `real_t coef = 1` )** [virtual]

Add consistent mass contribution to left-hand side.

Parameters

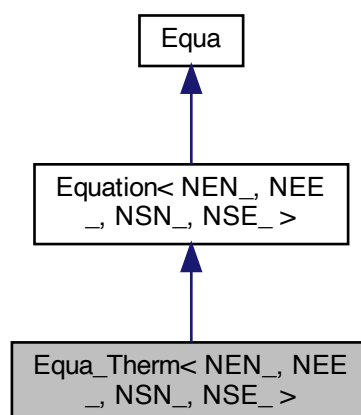

<code>in</code>	<code>coef</code>	coefficient to multiply by the matrix before adding [Default: 1]
-----------------	-------------------	--

Reimplemented in [Beam3DL2](#), [Elas2DT3](#), [Elas2DQ4](#), [Bar2DL2](#), and [Elas3DH8](#).

## 7.34 Equa\_Therm< NEN\_, NEE\_, NSN\_, NSE\_ > Class Template Reference

Abstract class for Heat transfer Finite Element classes.

Inheritance diagram for `Equa_Therm< NEN_, NEE_, NSN_, NSE_ >`:

Collaboration diagram for Equa\_Therm< NEN\_, NEE\_, NSN\_, NSE\_ >:

## Public Member Functions

### 7.34.1 Detailed Description

**template<size\_t NEN\_, size\_t NEE\_, size\_t NSN\_, size\_t NSE\_>class OFELI::Equa\_Therm< NEN\_, NEE\_, NSN\_, NSE\_ >**

Abstract class for Heat transfer Finite Element classes.  
Template Parameters

<code>&lt;NEN_&gt;</code>	Number of element nodes
<code>&lt;NEE_&gt;</code>	Number of element equations
<code>&lt;NSN_&gt;</code>	Number of side nodes
<code>&lt;NSE_&gt;</code>	Number of side equations

### 7.34.2 Constructor & Destructor Documentation

**Equa\_Therm ( )**

Default constructor.  
Constructs an empty equation.

### 7.34.3 Member Function Documentation

**virtual void setStab ( )** [virtual]

Set stabilized formulation.  
Stabilized variational formulations are to be used when the Péclet number is large.  
By default, no stabilization is used.

**virtual void LCapacity ( real\_t coef = 1 )** [virtual]

Add lumped capacity contribution to element matrix.  
Parameters

<code>in</code>	<code>coef</code>	coefficient to multiply by the matrix before adding [Default: 1]
-----------------	-------------------	--

Reimplemented in [DC2DT3](#), [DC1DL2](#), [DC3DT4](#), [DC3DAT3](#), and [DC2DT6](#).

**virtual void Capacity ( real\_t coef = 1 )** [virtual]

Add consistent capacity contribution to left-hand side.

### 7.34. EQUA\_THERM< NEN\_, NEE\_, NSN\_, NSE\_ > ~~CLASS TEMPLATE~~ ~~IMPLEMENTATION~~

Parameters

<b>in</b>	<i>coef</i>	coefficient to multiply by the matrix before adding [Default: 1]
-----------	-------------	--

Reimplemented in [DC2DT3](#), [DC1DL2](#), [DC3DT4](#), [DC3DAT3](#), and [DC2DT6](#).

**virtual void BodyRHS ( const Vect< real.t > &f )** [virtual]

Add body right-hand side term to right-hand side.

Parameters

<b>in</b>	<i>f</i>	Vector containing source at nodes.
-----------	----------	------------------------------------

Reimplemented in [DC2DT3](#), [DC3DT4](#), [DC1DL2](#), [DC2DT6](#), and [DC3DAT3](#).

**virtual void BoundaryRHS ( const Vect< real.t > &f )** [virtual]

Add boundary right-hand side term to right-hand side.

Parameters

<b>in</b>	<i>f</i>	Vector containing source at nodes.
-----------	----------	------------------------------------

Reimplemented in [DC2DT3](#), [DC3DT4](#), [DC2DT6](#), and [DC3DAT3](#).

**void build ( )**

Build the linear system of equations.

Before using this function, one must have properly selected appropriate options for:

- The choice of a steady state or transient analysis. By default, the analysis is stationary
- In the case of transient analysis, the choice of a time integration scheme and a lumped or consistent capacity matrix. If transient analysis is chosen, the lumped capacity matrix option is chosen by default, and the implicit Euler scheme is used by default for time integration.

**void build ( TimeStepping & s )**

Build the linear system of equations.

Before using this function, one must have properly selected appropriate options for:

- The choice of a steady state or transient analysis. By default, the analysis is stationary
- In the case of transient analysis, the choice of a time integration scheme and a lumped or consistent capacity matrix. If transient analysis is chosen, the lumped capacity matrix option is chosen by default, and the implicit Euler scheme is used by default for time integration.

Parameters

<b>in</b>	<i>s</i>	Reference to used <a href="#">TimeStepping</a> instance
-----------	----------	---

**void build ( EigenProblemSolver & e )**

Build the linear system for an eigenvalue problem.

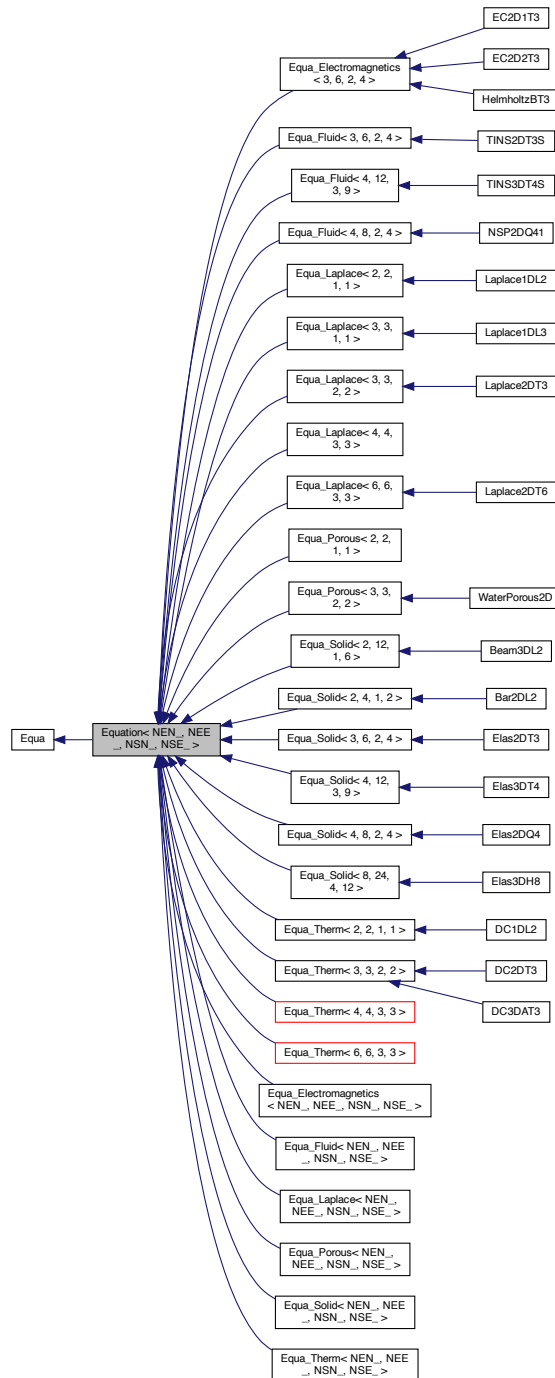

Parameters

in	<i>e</i>	Reference to used <a href="#">EigenProblemSolver</a> instance
----	----------	---

### 7.35.1 Detailed Description

`template<size_t NEN_, size_t NEE_, size_t NSN_, size_t NSE_>class OFELI::Equation< NEN_, NEE_, NSN_, NSE_ >`

Abstract class for all equation classes.

Template Arguments:

- `NEN_` : Number of element nodes
- `NEE_` : Number of element equations
- `NSN_` : Number of side nodes
- `NSN_` : Number of side equations

Author

Rachid Touzani

Copyright

GNU Lesser Public License

### 7.35.2 Constructor & Destructor Documentation

**Equation ( )**

Default constructor. Constructs an "empty" equation

**Equation ( Mesh & *mesh* )**

Constructor with mesh instance.

Parameters

<code>in</code>	<code>mesh</code>	<a href="#">Mesh</a> instance
-----------------	-------------------	-------------------------------

**Equation ( Mesh & *mesh*, Vect< real\_t > & *u* )**

Constructor with mesh instance and solution vector.

Parameters

<code>in</code>	<code>mesh</code>	<a href="#">Mesh</a> instance
-----------------	-------------------	-------------------------------

in	<i>u</i>	<a href="#">Vect</a> instance containing solution.
----	----------	--

**Equation ( Mesh & *mesh*, Vect< real.t > & *u*, real.t & *init\_time*, real.t & *final\_time*, real.t & *time\_step* )**

Constructor with mesh instance, matrix and right-hand side.

Parameters

in	<i>mesh</i>	<a href="#">Mesh</a> instance
in	<i>u</i>	<a href="#">Vect</a> instance containing Right-hand side.
in	<i>init_time</i>	Initial Time value
in	<i>final_time</i>	Final Time value
in	<i>time_step</i>	Time step value

### 7.35.3 Member Function Documentation

**void updateBC ( const Element & *el*, const Vect< real.t > & *bc* )**

Update Right-Hand side by taking into account essential boundary conditions.

Parameters

in	<i>el</i>	Reference to current element instance
in	<i>bc</i>	Vector that contains imposed values at all DOFs

**void DiagBC ( DOFSupport *dof\_type* = NODE\_DOF, int *dof* = 0 )**

Update element matrix to impose bc by diagonalization technique.

Parameters

in	<i>dof_type</i>	DOF type option. To choose among the enumerated values: <ul style="list-style-type: none"> <li>• NODE_DOF, DOFs are supported by nodes [Default]</li> <li>• ELEMENT_DOF, DOFs are supported by elements</li> <li>• SIDE_DOF, DOFs are supported by sides</li> </ul>
in	<i>dof</i>	DOF setting: <ul style="list-style-type: none"> <li>• = 0, All DOFs are taken into account [Default]</li> <li>• != 0, Only DOF No. <i>dof</i> is handled in the system</li> </ul>

**void LocalNodeVector ( Vect< real.t > & *b* )**

Localize [Element](#) Vector from a [Vect](#) instance.

Parameters

in	<i>b</i>	Reference to global vector to be localized. The resulting local vector can be accessed by attribute ePrev. This member function is to be used if a constructor with <a href="#">Element</a> was invoked.
----	----------	--

**void ElementNodeVector ( const Vect< real\_t > & *b*, LocalVect< real\_t, NEE\_ > & *be* )**

Localize [Element](#) Vector from a [Vect](#) instance.

Parameters

in	<i>b</i>	Global vector to be localized.
out	<i>be</i>	Local vector, the length of which is the total number of element equations.

Remarks

All degrees of freedom are transferred to the local vector

**void SideNodeVector ( const Vect< real.t > & b, LocalVect< real.t, NSE\_ > & bs )**

Localize [Side](#) Vector from a [Vect](#) instance.

Parameters

in	<i>b</i>	Global vector to be localized.
out	<i>bs</i>	Local vector, the length of which is the total number of side equations.

Remarks

All degrees of freedom are transferred to the local vector

**void SideSideVector ( const Vect< real.t > & b, real.t \* bs )**

Localize [Side](#) Vector from a [Vect](#) instance.

Parameters

in	<i>b</i>	Global vector to be localized.
out	<i>bs</i>	Local constant value of vector at given side.

Remarks

All degrees of freedom are transferred to the local vector

**void ElementNodeVectorSingleDOF ( const Vect< real.t > & b, LocalVect< real.t, NEN\_ > & be )**

Localize [Element](#) Vector from a [Vect](#) instance.

Parameters

in	<i>b</i>	Global vector to be localized.
out	<i>be</i>	Local vector, the length of which is the total number of element equations.

Remarks

Vector b is assumed to contain only one degree of freedom by node.

**void ElementNodeVector ( const Vect< real.t > & b, LocalVect< real.t, NEN\_ > & be, int dof )**

Localize [Element](#) Vector from a [Vect](#) instance.

Parameters

<code>in</code>	<code>b</code>	Global vector to be localized.
<code>out</code>	<code>be</code>	Local vector, the length of which is the total number of element equations.
<code>in</code>	<code>dof</code>	Degree of freedom to transfer to the local vector

Remarks

Only yhe dega dof is transferred to the local vector

**void ElementSideVector ( const Vect< real.t > & b, LocalVect< real.t, NSE\_ > & be )**

Localize [Element](#) Vector from a [Vect](#) instance.

Parameters

<code>in</code>	<code>b</code>	Global vector to be localized.
<code>out</code>	<code>be</code>	Local vector, the length of which is

**void ElementVector ( const Vect< real.t > & b, DOFSupport dof\_type = NODE\_DOF, int flag = 0 )**

Localize [Element](#) Vector.

Parameters

<code>in</code>	<code>b</code>	Global vector to be localized
<code>in</code>	<code>dof_type</code>	DOF type option. To choose among the enumerated values: <ul style="list-style-type: none"> <li>• <code>NODE_DOF</code>, DOFs are supported by nodes [Default]</li> <li>• <code>ELEMENT_DOF</code>, DOFs are supported by elements</li> <li>• <code>SIDE_DOF</code>, DOFs are supported by sides</li> </ul>
<code>in</code>	<code>flag</code>	Option to set: <ul style="list-style-type: none"> <li>• <code>= 0</code>, All DOFs are taken into account [Default]</li> <li>• <code>!= 0</code>, Only DOF number <code>dof</code> is handled in the system</li> </ul> <p>The resulting local vector can be accessed by attribute <code>ePrev</code>.</p>

Remarks

This member function is to be used if a constructor with [Element](#) was invoked. It uses the [Element](#) pointer `_theElement`

**void SideVector ( const Vect< real.t > & b, real.t \* sb )**

Localize [Side](#) Vector.

Parameters

in	<i>b</i>	Global vector to be localized <ul style="list-style-type: none"> <li>• NODE_DOF, DOFs are supported by nodes [ default ]</li> <li>• ELEMENT_DOF, DOFs are supported by elements</li> <li>• SIDE_DOF, DOFs are supported by sides</li> <li>• BOUNDARY_SIDE_DOF, DOFs are supported by boundary sides</li> </ul>
out	<i>sb</i>	Array in which local vector is stored The resulting local vector can be accessed by attribute ePrev.

## Remarks

This member function is to be used if a constructor with [Side](#) was invoked. It uses the [Side](#) pointer `_theSide`

**void ElementNodeCoordinates ( )**

Localize coordinates of element nodes.

Coordinates are stored in array `_x[0]`, `_x[1]`, ... which are instances of class [Point<real\\_t>](#)

## Remarks

This member function uses the [Side](#) pointer `_theSide`

**void SideNodeCoordinates ( )**

Localize coordinates of side nodes.

Coordinates are stored in array `_x[0]`, `_x[1]`, ... which are instances of class [Point<real\\_t>](#)

## Remarks

This member function uses the [Element](#) pointer `_theElement`

**void ElementAssembly ( Matrix< real\_t > \* A )**

Assemble element matrix into global one.

Parameters

<i>A</i>	Pointer to global matrix (abstract class: can be any of classes <a href="#">SkSMatrix</a> , <a href="#">SkMatrix</a> , <a href="#">SpMatrix</a> )
----------	---

## Warning

The element pointer is given by the global variable `theElement`

**void ElementAssembly ( BMatrix< real\_t > & A )**

Assemble element matrix into global one.

Parameters

$A$	Global matrix stored as a <a href="#">BMatrix</a> instance
-----	--

Warning

The element pointer is given by the global variable `theElement`

**void ElementAssembly ( SkSMatrix< real\_t > & A )**

Assemble element matrix into global one.

Parameters

$A$	Global matrix stored as an <a href="#">SkSMatrix</a> instance
-----	---

Warning

The element pointer is given by the global variable `theElement`

**void ElementAssembly ( SkMatrix< real\_t > & A )**

Assemble element matrix into global one.

Parameters

<code>in</code>	$A$	Global matrix stored as an <a href="#">SkMatrix</a> instance
-----------------	-----	--

Warning

The element pointer is given by the global variable `theElement`

**void ElementAssembly ( SpMatrix< real\_t > & A )**

Assemble element matrix into global one.

Parameters

<code>in</code>	$A$	Global matrix stored as an <a href="#">SpMatrix</a> instance
-----------------	-----	--

Warning

The element pointer is given by the global variable `theElement`

**void ElementAssembly ( TrMatrix< real\_t > & A )**

Assemble element matrix into global one.

Parameters

<code>in</code>	$A$	Global matrix stored as an <a href="#">TrMatrix</a> instance
-----------------	-----	--

Warning

The element pointer is given by the global variable `theElement`

**void DGElementAssembly ( Matrix< real\_t > \* A )**

Assemble element matrix into global one for the Discontinuous Galerkin approximation.

Parameters

$A$	Pointer to global matrix (abstract class: can be any of classes <a href="#">SkSMatrix</a> , <a href="#">SkMatrix</a> , <a href="#">SpMatrix</a> )
-----	---

Warning

The element pointer is given by the global variable `theElement`

**void DGElementAssembly ( SkSMatrix< real.t > & A )**

Assemble element matrix into global one for the Discontinuous Galerkin approximation.

Parameters

$A$	Global matrix stored as an <a href="#">SkSMatrix</a> instance
-----	---

Warning

The element pointer is given by the global variable `theElement`

**void DGElementAssembly ( SkMatrix< real.t > & A )**

Assemble element matrix into global one for the Discontinuous Galerkin approximation.

Parameters

in	$A$	Global matrix stored as an <a href="#">SkMatrix</a> instance
----	-----	--

Warning

The element pointer is given by the global variable `theElement`

**void DGElementAssembly ( SpMatrix< real.t > & A )**

Assemble element matrix into global one for the Discontinuous Galerkin approximation.

Parameters

in	$A$	Global matrix stored as an <a href="#">SpMatrix</a> instance
----	-----	--

Warning

The element pointer is given by the global variable `theElement`

**void DGElementAssembly ( TrMatrix< real.t > & A )**

Assemble element matrix into global one for the Discontinuous Galerkin approximation.

Parameters

in	$A$	Global matrix stored as an <a href="#">TrMatrix</a> instance
----	-----	--

Warning

The element pointer is given by the global variable `theElement`

**void SideAssembly ( Matrix< real.t > \* A )**

Assemble side (edge or face) matrix into global one.

Parameters

$A$	Pointer to global matrix (abstract class: can be any of classes <a href="#">SkMatrix</a> , <a href="#">SkMatrix</a> , <a href="#">SpMatrix</a> )
-----	--

Warning

The side pointer is given by the global variable `theSide`

**void SideAssembly ( SkMatrix< real.t > & A )**

Assemble side (edge or face) matrix into global one.

Parameters

in	$A$	Global matrix stored as an <a href="#">SkMatrix</a> instance
----	-----	--

Warning

The side pointer is given by the global variable `theSide`

**void SideAssembly ( SkMatrix< real.t > & A )**

Assemble side (edge or face) matrix into global one.

Parameters

in	$A$	Global matrix stored as an <a href="#">SkMatrix</a> instance
----	-----	--

Warning

The side pointer is given by the global variable `theSide`

**void SideAssembly ( SpMatrix< real.t > & A )**

Assemble side (edge or face) matrix into global one.

Parameters

in	$A$	Global matrix stored as an <a href="#">SpMatrix</a> instance
----	-----	--

Warning

The side pointer is given by the global variable `theSide`

**void ElementAssembly ( Vect< real.t > & v )**

Assemble element vector into global one.

Parameters

in	$v$	Global vector ( <a href="#">Vect</a> instance)
----	-----	--

Warning

The element pointer is given by the global variable `theElement`

**void SideAssembly ( Vect< real.t > & v )**

Assemble side (edge or face) vector into global one.

Parameters

in	$v$	Global vector ( <a href="#">Vect</a> instance)
----	-----	--

Warning

The side pointer is given by the global variable `theSide`

**void AxbAssembly ( const Element & *el*, const Vect< real\_t > & *x*, Vect< real\_t > & *b* )**

Assemble product of element matrix by element vector into global vector.

Parameters

in	<i>el</i>	Reference to <a href="#">Element</a> instance
in	<i>x</i>	Global vector to multiply by ( <a href="#">Vect</a> instance)
out	<i>b</i>	Global vector to add ( <a href="#">Vect</a> instance)

**void AxbAssembly ( const Side & *sd*, const Vect< real\_t > & *x*, Vect< real\_t > & *b* )**

Assemble product of side matrix by side vector into global vector.

Parameters

in	<i>sd</i>	Reference to <a href="#">Side</a> instance
in	<i>x</i>	Global vector to multiply by ( <a href="#">Vect</a> instance)
out	<i>b</i>	Global vector ( <a href="#">Vect</a> instance)

**real\_t setMaterialProperty ( const string & *exp*, const string & *prop* )**

Define a material property by an algebraic expression.

Parameters

in	<i>exp</i>	Algebraic expression
in	<i>prop</i>	Property name

Returns

Return value in expression evaluation:

- =0, Normal evaluation
- !=0, An error message is displayed

## 7.36 Estimator Class Reference

To calculate an a posteriori estimator of the solution.

### 7.36.1 Detailed Description

To calculate an a posteriori estimator of the solution.

This class enables calculating an estimator of a solution in order to evaluate reliability. Estimation uses the so-called Zienkiewicz-Zhu estimator.

Author

Rachid Touzani

Copyright

GNU Lesser Public License

### 7.36.2 Member Enumeration Documentation

**enum EstimatorType**

Enumerate variable that selects an error estimator for mesh adaptation purposes

Enumerator

*ESTIM\_ZZ* Zhu-Zienckiewicz elementwise estimator

*ESTIM\_ND\_JUMP* Normal derivative jump sidewise estimator

### 7.36.3 Constructor & Destructor Documentation

**Estimator** ( [Mesh](#) & *m* )

Constructor using finite element mesh.

Parameters

in	<i>m</i>	<a href="#">Mesh</a> instance
----	----------	-------------------------------

### 7.36.4 Member Function Documentation

**void setType ( EstimatorType *t* = ESTIM\_ZZ )**

Select type of a posteriori estimator.

Parameters

in	<i>t</i>	Type of estimator. It has to be chosen among the enumerated values: <ul style="list-style-type: none"> <li>• ESTIM_ZZ: The Zhu-Zienckiewicz estimator (Default value)</li> <li>• ESTIM_ND_JUMP: An estimator based on the jump of normal derivatives of the solution across mesh sides</li> </ul>
----	----------	---

**void setSolution ( const Vect< real\_t > & *u* )**

Provide solution vector in order to determine error index.

Parameters

in	<i>u</i>	Vector containing solution at mesh nodes
----	----------	--

**void getElementWiseIndex ( Vect< real\_t > & *e* )**

Get vector containing elementwise error index.

Parameters

in,out	<i>e</i>	Vector that contains once the member function setError is invoked a posteriori estimator at each element
--------	----------	--

**void getNodeWiseIndex ( Vect< real\_t > & *e* )**

Get vector containing nodewise error index.

Parameters

in,out	<i>e</i>	Vector that contains once the member function setError is invoked a posteriori estimator at each node
--------	----------	---

**void getSideWiseIndex ( Vect< real\_t > & *e* )**

Get vector containing sidewise error index.

Parameters

in,out	<i>e</i>	Vector that contains once the member function setError is invoked a posteriori estimator at each side
--------	----------	---

### 7.37.1 Detailed Description

class for the fast marching algorithm on uniform grids

This class implements the Fast Marching method to solve the eikonal equation in a uniform grid (1-D, 2-D or 3-D). In other words, the class solves the partial differential equation  $|\nabla u|F = 1$  with  $u = 0$  on the interface, where  $F$  is the velocity

### 7.37.2 Constructor & Destructor Documentation

#### **FastMarching ( )**

Default Constructor.

Initializes to default value grid data

#### **FastMarching ( const Grid & g, Vect< real.t > & T )**

Constructor using grid data.

Constructor using [Grid](#) instance

Parameters

in	$g$	Instance of class <a href="#">Grid</a>
in	$T$	Vector containing the on input an initialization of the distance function and once the function run is invoked the distance at grid nodes. The initialization vector must use the following rules: <ul style="list-style-type: none"> <li>• The solution must be supplied at all grid points in the vicinity of the interface(s).</li> <li>• All other grid nodes must have the value INFINITY wth positive value if the node is in an outer domain and negative if it is in an inner domain</li> </ul>

#### **FastMarching ( const Grid & g, Vect< real.t > & T, Vect< real.t > & F )**

Constructor.

Constructor using [Grid](#) instance and propagation speed

Parameters

in	$g$	Instance of class <a href="#">Grid</a>
in	$T$	Vector containing the on input an initialization of the distance function and once the function run is invoked the distance at grid nodes. The initialization vector must use the following rules: <ul style="list-style-type: none"> <li>• The solution must be supplied at all grid points in the vicinity of the interface(s).</li> <li>• All other grid nodes must have the value INFINITY wth positive value if the node is in an outer domain and negative if it is in an inner domain</li> </ul>
in	$F$	Vector containing propagation speed at grid nodes

### 7.37.3 Member Function Documentation

**void set ( const Grid & g, Vect< real\_t > & T )**

Define grid and solution vector.

This function is to be used if the default constructor has been used

Parameters

in	<i>g</i>	Instance of class <a href="#">Grid</a>
in	<i>T</i>	Vector containing the on input an initialization of the distance function and once the function run is invoked the distance at grid nodes. The initialization vector must use the following rules: <ul style="list-style-type: none"> <li>• The solution must be supplied at all grid points in the vicinity of the interface(s).</li> <li>• All other grid nodes must have the value INFINITY with positive value if the node is in an outer domain and negative if it is in an inner domain</li> </ul>

**void set ( const Grid & g, Vect< real\_t > & T, Vect< real\_t > & F )**

Define grid, solution vector and prppagation speed.

This function is to be used if the default constructor has been used

Parameters

in	<i>g</i>	Instance of class <a href="#">Grid</a>
in	<i>T</i>	Vector containing the on input an initialization of the distance function and once the function run is invoked the distance at grid nodes. The initialization vector must use the following rules: <ul style="list-style-type: none"> <li>• The solution must be supplied at all grid points in the vicinity of the interface(s).</li> <li>• All other grid nodes must have the value INFINITY with positive value if the node is in an outer domain and negative if it is in an inner domain</li> </ul>
in	<i>F</i>	Vector containing propagation speed at grid nodes

**int run ( )**

Execute Fast Marching Procedure.

Once this function is invoked, the vector T in the constructor or in the member function set contains the solution.

Returns

Return value:

- = 0 if solution has been normally computed
- != 0 An error has occurred

**real\_t** getResidual ( )

Check consistency by computing the discrete residual.

This function returns residual error ( $||\nabla u|^2|F|-1|$ )

### 7.38.1 Detailed Description

class for the fast marching algorithm on 1-D uniform grids

This class implements the Fast Marching method to solve the eikonal equation in a 1-D uniform grid. In other words, the class solves the partial differential equation  $|T'|F = 1$  with  $T = 0$  on the interface, where  $F$  is the velocity

### 7.38.2 Constructor & Destructor Documentation

**FastMarching1DG ( )**

Default Constructor.

Initializes to default value grid data

**FastMarching1DG ( const `Grid` &`g`, `Vect`< `real_t` > &`T` )**

Constructor using grid data.

Constructor using `Grid` instance

Parameters

in	<code>g</code>	Instance of class <code>Grid</code>
in	<code>T</code>	Vector containing the on input an initialization of the distance function and once the function run is invoked the distance at grid nodes. The initialization vector must use the following rules: <ul style="list-style-type: none"> <li>• The solution must be supplied at all grid points in the vicinity of the interface(s).</li> <li>• All other grid nodes must have the value INFINITY wth positive value if the node is in an outer domain and negative if it is in an inner domain</li> </ul>

**FastMarching1DG ( const `Grid` &`g`, `Vect`< `real_t` > &`T`, `Vect`< `real_t` > &`F` )**

Constructor.

Constructor using `Grid` instance and propagation speed

Parameters

in	<code>g</code>	Instance of class <code>Grid</code>
----	----------------	-------------------------------------

in	$T$	Vector containing the on input an initialization of the distance function and once the function run is invoked the distance at grid nodes. The initialization vector must use the following rules: <ul style="list-style-type: none"> <li>• The solution must be supplied at all grid points in the vicinity of the interface(s).</li> <li>• All other grid nodes must have the value INFINITY with positive value if the node is in an outer domain and negative if it is in an inner domain</li> </ul>
in	$F$	Vector containing propagation speed at grid nodes

### 7.38.3 Member Function Documentation

**void set ( const Grid & g, Vect< real\_t > & T )**

Define grid and solution vector.

This function is to be used if the default constructor has been used

Parameters

in	$g$	Instance of class <a href="#">Grid</a>
in	$T$	Vector containing the on input an initialization of the distance function and once the function run is invoked the distance at grid nodes. The initialization vector must use the following rules: <ul style="list-style-type: none"> <li>• The solution must be supplied at all grid points in the vicinity of the interface(s).</li> <li>• All other grid nodes must have the value INFINITY with positive value if the node is in an outer domain and negative if it is in an inner domain</li> </ul>

**void set ( const Grid & g, Vect< real\_t > & T, Vect< real\_t > & F )**

Define grid, solution vector and prppagation speed.

This function is to be used if the default constructor has been used

Parameters

in	$g$	Instance of class <a href="#">Grid</a>
in	$T$	Vector containing the on input an initialization of the distance function and once the function run is invoked the distance at grid nodes. The initialization vector must use the following rules: <ul style="list-style-type: none"> <li>• The solution must be supplied at all grid points in the vicinity of the interface(s).</li> <li>• All other grid nodes must have the value INFINITY with positive value if the node is in an outer domain and negative if it is in an inner domain</li> </ul>

<code>in</code>	$F$	Vector containing propagation speed at grid nodes
-----------------	-----	---

**int run ( )**

Execute Fast Marching Procedure.

Once this function is invoked, the vector `phi` in the constructor or in the member function `set` contains the solution.

Returns

Return value:

- `= 0` if solution has been normally computed
- `!= 0` An error has occurred

**real\_t getResidual ( )**

Check consistency by computing the discrete residual.

This function returns residual error ( $||T'F|-1||$ )

*Return shape function of node  $i$  at given point.*

- **real\_t Sh** (size\_t *i*, Point< real\_t > *s*) const  
*Calculate shape function of node i at a given point s.*
- **real\_t getDet** () const  
*Return determinant of jacobian.*
- **Point< real\_t > getCenter** () const  
*Return coordinates of center of element.*
- **Point< real\_t > getLocalPoint** () const  
*Localize a point in the element.*
- **Point< real\_t > getLocalPoint** (const Point< real\_t > &*s*) const  
*Localize a point in the element.*

### 7.41.1 Detailed Description

Parent class from which inherit all finite element shape classes.

Author

Rachid Touzani

Copyright

GNU Lesser Public License

### 7.41.2 Constructor & Destructor Documentation

**FEShape ( const Element \* *el* )**

Constructor for an element.

Parameters

in	<i>el</i>	Pointer to element
----	-----------	--------------------

**FEShape ( const Side \* *sd* )**

Constructor for a side.

Parameters

in	<i>sd</i>	Pointer to side
----	-----------	-----------------

### 7.41.3 Member Function Documentation

**real\_t Sh ( size\_t *i*, Point< real\_t > *s* ) const**

Calculate shape function of node *i* at a given point *s*.

Parameters

in	<i>i</i>	Local node label
in	<i>s</i>	Point in the reference triangle where the shape function is evaluated

**real\_t getDet ( ) const**

Return determinant of jacobian.

If the transformation (Reference element -> Actual element) is not affine, member function **setLocal()** must have been called before in order to calculate relevant quantities.

**Point<real\_t> getLocalPoint ( ) const**

Localize a point in the element.

Return actual coordinates in the reference element. If the transformation (Reference element -> Actual element) is not affine, member function **setLocal()** must have been called before in order to calculate relevant quantities.

**Point<real\_t> getLocalPoint ( const Point< real\_t > &s ) const**

Localize a point in the element.

Return actual coordinates where s are coordinates in the reference element.

## 7.42 Figure Class Reference

To store and treat a figure (or shape) information.

Inheritance diagram for Figure:

### Public Member Functions

- **Figure ()**  
*Default constructor.*
- **Figure (const Figure &f)**  
*Copy constructor.*
- **virtual ~Figure ()**  
*Destructor.*
- **void setCode (int code)**  
*Choose a code for the domain defined by the figure.*
- **virtual real\_t getSignedDistance (const Point< real\_t > &p) const**  
*Return signed distance from a given point to current figure.*
- **Figure & operator= (const Figure &f)**  
*Operator =.*
- **void getSignedDistance (const Grid &g, Vect< real\_t > &d) const**  
*Calculate signed distance to current figure with respect to grid points.*
- **real\_t dLine (const Point< real\_t > &p, const Point< real\_t > &a, const Point< real\_t > &b) const**  
*Compute signed distance from a line.*

### 7.42.1 Detailed Description

To store and treat a figure (or shape) information.

This class is essentially useful to construct data for mesh generators and for distance calculations.

Author

Rachid Touzani

Copyright

GNU Lesser Public License

### 7.42.2 Member Function Documentation

**virtual real\_t getSignedDistance ( const Point< real\_t > & p ) const** [virtual]

Return signed distance from a given point to current figure.

Parameters

in	<i>p</i>	<a href="#">Point</a> instance from which distance is computed
----	----------	--

Reimplemented in [Polygon](#), [Triangle](#), [Ellipse](#), [Sphere](#), [Circle](#), [Brick](#), and [Rectangle](#).

**void getSignedDistance ( const Grid & g, Vect< real\_t > & d ) const**

Calculate signed distance to current figure with respect to grid points.

Parameters

in	<i>g</i>	<a href="#">Grid</a> instance
in	<i>d</i>	<a href="#">Vect</a> instance containing calculated distance from each grid index to <a href="#">Figure</a>

Remarks

Vector d doesn't need to be sized before invoking this function

**real\_t dLine ( const Point< real\_t > & p, const Point< real\_t > & a, const Point< real\_t > & b ) const**

Compute signed distance from a line.

Parameters

in	<i>p</i>	<a href="#">Point</a> for which distance is computed
in	<i>a</i>	First vertex of line
in	<i>b</i>	Second vertex of line

Returns

Signed distance

## 7.43 Funct Class Reference

A simple class to parse real valued functions.

### 7.43.1 Detailed Description

A simple class to parse real valued functions.

Functions must have 1, 2, 3 or at most 4 variables.

Warning

Data in the file must be listed in the following order:

```
for x=x_0,...,x_I
  for y=y_0,...,y_J
    for z=z_0,...,z_K
      read v(x,y,z)
```

### 7.43.2 Constructor & Destructor Documentation

**Func** ( string v )

Constructor for a function of one variable.

Parameters

<code>in</code>	<code>v</code>	Name of the variable
-----------------	----------------	----------------------

**Func ( string *v1*, string *v2* )**

Constructor for a function of two variables.

Parameters

<code>in</code>	<code>v1</code>	Name of the first variable
<code>in</code>	<code>v2</code>	Name of the second variable

**Func ( string *v1*, string *v2*, string *v3* )**

Constructor for a function of three variables.

Parameters

<code>in</code>	<code>v1</code>	Name of the first variable
<code>in</code>	<code>v2</code>	Name of the second variable
<code>in</code>	<code>v3</code>	Name of the third variable

**Func ( string *v1*, string *v2*, string *v3*, string *v4* )**

Constructor for a function of four variables.

Parameters

<code>in</code>	<code>v1</code>	Name of the first variable
<code>in</code>	<code>v2</code>	Name of the second variable
<code>in</code>	<code>v3</code>	Name of the third variable
<code>in</code>	<code>v4</code>	Name of the fourth variable

### 7.43.3 Member Function Documentation

**void operator= ( string *e* )**

Operator =.

Define the function by an algebraic expression

Parameters

<code>in</code>	<code>e</code>	Algebraic expression defining the function.
-----------------	----------------	---

## 7.44 Gauss Class Reference

Calculate data for Gauss integration.

### Public Member Functions

- [Gauss](#) ()  
*Default constructor.*
- [Gauss](#) (size\_t np)  
*Constructor using number of [Gauss](#) points.*
- void [setNbPoints](#) (size\_t np)

*Set number of integration points.*

- void `setTriangle` (`LocalVect`< `real_t`, 7 > &`w`, `LocalVect`< `Point`< `real_t` >, 7 > &`x`)

*Choose integration on triangle (7-point formula)*

- `real_t` `x` (size\_t `i`) const

*Return coordinate of  $i$ -th Gauss-Legendre point.*

- const `Point`< `real_t` > & `xt` (size\_t `i`) const

*Return coordinates of points in the reference triangle.*

- `real_t` `w` (size\_t `i`) const

*Return weight of  $i$ -th Gauss-Legendre point.*

### 7.44.1 Detailed Description

Calculate data for Gauss integration.

Author

Rachid Touzani

Copyright

GNU Lesser Public License

### 7.44.2 Constructor & Destructor Documentation

`Gauss` ( size\_t `np` )

Constructor using number of `Gauss` points.

Parameters

<code>in</code>	<code>np</code>	Number of integration points
-----------------	-----------------	------------------------------

### 7.44.3 Member Function Documentation

void `setTriangle` ( `LocalVect`< `real_t`, 7 > & `w`, `LocalVect`< `Point`< `real_t` >, 7 > & `x` )

Choose integration on triangle (7-point formula)

If this is not selected, `Gauss` integration formula on  $[-1, 1]$  is calculated.

Parameters

<code>out</code>	<code>w</code>	Array of weights of integration points
<code>out</code>	<code>x</code>	Array of coordinates of integration points

## 7.45 Grid Class Reference

To manipulate structured grids.

### Public Member Functions

- `Grid` ()

*Construct a default grid with 10 intervals in each direction.*

- `Grid` (`real_t` `xm`, `real_t` `xM`, size\_t `np`)

*Construct a 1-D structured grid given its extremal coordinates and number of intervals.*

- `Grid (real_t xm, real_t xM, real_t ym, real_t yM, size_t npx, size_t npy)`  
Construct a 2-D structured grid given its extremal coordinates and number of intervals.
- `Grid (Point< real_t > m, Point< real_t > M, size_t npx, size_t npy)`  
Construct a 2-D structured grid given its extremal coordinates and number of intervals.
- `Grid (real_t xm, real_t xM, real_t ym, real_t yM, real_t zm, real_t zM, size_t npx, size_t npy, size_t npz)`  
Construct a 3-D structured grid given its extremal coordinates and number of intervals.
- `Grid (Point< real_t > m, Point< real_t > M, size_t npx, size_t npy, size_t npz)`  
Construct a 3-D structured grid given its extremal coordinates and number of intervals.
- `void setXMin (const Point< real_t > &x)`  
Set min. coordinates of the domain.
- `void setXMax (const Point< real_t > &x)`
- `void setDomain (real_t xmin, real_t xmax)`  
Set Dimensions of the domain: 1-D case.
- `void setDomain (real_t xmin, real_t xmax, real_t ymin, real_t ymax)`  
Set Dimensions of the domain: 2-D case.
- `void setDomain (real_t xmin, real_t xmax, real_t ymin, real_t ymax, real_t zmin, real_t zmax)`  
Set Dimensions of the domain: 3-D case.
- `void setDomain (Point< real_t > xmin, Point< real_t > xmax)`  
Set Dimensions of the domain: 3-D case.
- `const Point< real_t > &getXMin () const`  
Return min. Coordinates of the domain.
- `const Point< real_t > &getXMax () const`  
Return max. Coordinates of the domain.
- `void setN (size_t nx, size_t ny=0, size_t nz=0)`  
Set number of grid intervals in the  $x$ ,  $y$  and  $z$ -directions.
- `void setNbDOF (size_t n)`  
Set number of degrees of freedom for a node [Default: 1].
- `size_t getNx () const`  
Return number of grid intervals in the  $x$ -direction.
- `size_t getNy () const`  
Return number of grid intervals in the  $y$ -direction.
- `size_t getNz () const`  
Return number of grid intervals in the  $z$ -direction.
- `real_t getHx () const`  
Return grid size in the  $x$ -direction.
- `real_t getHy () const`  
Return grid size in the  $y$ -direction.
- `real_t getHz () const`  
Return grid size in the  $z$ -direction.
- `Point< real_t > getCoord (size_t i) const`  
Return coordinates a point with label  $i$  in a 1-D grid.
- `Point< real_t > getCoord (size_t i, size_t j) const`  
Return coordinates a point with label  $(i, j)$  in a 2-D grid.
- `Point< real_t > getCoord (size_t i, size_t j, size_t k) const`  
Return coordinates a point with label  $(i, j, k)$  in a 3-D grid.
- `size_t getNbNodes () const`

- Return total number of grid nodes.*

  - `size_t getNbDOF () const`
- Return total number of dof.*

  - `real_t getX (size_t i) const`
- Return x-coordinate of point with index  $i$*

  - `real_t getY (size_t j) const`
- Return y-coordinate of point with index  $j$*

  - `real_t getZ (size_t k) const`
- Return z-coordinate of point with index  $k$*

  - `Point2D< real_t > getXY (size_t i, size_t j) const`
- Return coordinates of point with indices  $(i, j)$*

  - `Point< real_t > getXYZ (size_t i, size_t j, size_t k) const`
- Return coordinates of point with indices  $(i, j, k)$*

  - `real_t getCenter (size_t i) const`
- Return coordinates of center of a 1-D cell with indices  $i, i+1$*

  - `Point< real_t > getCenter (size_t i, size_t j) const`
- Return coordinates of center of a 2-D cell with indices  $(i, j), (i+1, j), (i+1, j+1), (i, j+1)$*

  - `Point< real_t > getCenter (size_t i, size_t j, size_t k) const`
- Return coordinates of center of a 3-D cell with indices  $(i, j, k), (i+1, j, k), (i+1, j+1, k), (i, j+1, k), (i, j, k+1), (i+1, j, k+1), (i+1, j+1, k+1), (i, j+1, k+1)$*

  - `void setCode (string exp, int code)`
- Set a code for some grid points.*

  - `void setCode (int side, int code)`
- Set a code for grid points on sides.*

  - `int getCode (int side) const`
- Return code for a side number.*

  - `int getCode (size_t i, size_t j) const`
- Return code for a grid point.*

  - `int getCode (size_t i, size_t j, size_t k) const`
- Return code for a grid point.*

  - `size_t getDim () const`
- Return space dimension.*

  - `void Deactivate (size_t i)`
- Change state of a cell from active to inactive (1-D grid)*

  - `void Deactivate (size_t i, size_t j)`
- Change state of a cell from active to inactive (2-D grid)*

  - `void Deactivate (size_t i, size_t j, size_t k)`
- Change state of a cell from active to inactive (2-D grid)*

  - `int isActive (size_t i) const`
- Say if cell is active or not (1-D grid)*

  - `int isActive (size_t i, size_t j) const`
- Say if cell is active or not (2-D grid)*

  - `int isActive (size_t i, size_t j, size_t k) const`
- Say if cell is active or not (3-D grid)*

### 7.45.1 Detailed Description

To manipulate structured grids.

### 7.46.1 Detailed Description

Builds finite element arrays for Helmholtz equations in a bounded media using 3-Node triangles.

Problem being formulated in time harmonics, the solution is complex-valued but stored in 2-degree of freedom real-valued vector. Therefore, mesh must be defined with 2 degrees of freedom per node

*Return gradient of a function defined at element nodes.*

### 7.47.1 Detailed Description

Defines a three-dimensional 8-node hexahedral finite element using Q1-isoparametric interpolation.

The reference element is the cube  $[-1, 1] \times [-1, 1] \times [-1, 1]$ . The user must take care to the fact that determinant of jacobian and other quantities depend on the point in the reference element where they are calculated. For this, before any utilization of shape functions or jacobian, function [getLocal\(s\)](#) must be invoked.

Author

Rachid Touzani

Copyright

GNU Lesser Public License

## 7.47.2 Member Function Documentation

**void setLocal ( const Point< real.t > & s )**

Initialize local point coordinates in element.

Parameters

in	s	<a href="#">Point</a> in the reference element This function computes jacobian, shape functions and their partial derivatives at s. Other member functions only return these values.
----	---	--

**void atGauss ( int n, std::vector< Point< real.t > > & dsh, std::vector< real.t > & w )**

Calculate shape function derivatives and integration weights.

Parameters

in	n	Number of Gauss-Legendre integration points in each direction
in	dsh	Vector of shape function derivatives at the <a href="#">Gauss</a> points
in	w	Weights of integration formula at <a href="#">Gauss</a> points

**void atGauss ( int n, std::vector< real.t > & sh, std::vector< real.t > & w )**

Calculate shape functions and integration weights.

Parameters

in	n	Number of Gauss-Legendre integration points in each direction
in	sh	Vector of shape functions at the <a href="#">Gauss</a> points
in	w	Weights of integration formula at <a href="#">Gauss</a> points

**Point<real.t> Grad ( const LocalVect< real.t, 8 > & u, const Point< real.t > & s )**

Return gradient of a function defined at element nodes.

Parameters

in	u	Vector of values at nodes
in	s	Local coordinates (in $[-1, 1] * [-1, 1] * [-1, 1]$ ) of point where the gradient is evaluated

Returns

Value of gradient

Note

If the derivatives of shape functions were not computed before calling this function (by calling setLocal), this function will compute them

## Additional Inherited Members

### 7.48.1 Detailed Description

Class to solve the Inviscid compressible fluid flows (Euler equations) for perfect gas in 1-D.

Solution method is a second-order MUSCL Finite Volume scheme

Author

S. Clain, V. Clauzon

Copyright

GNU Lesser Public License

### 7.48.2 Constructor & Destructor Documentation

`ICPG1D ( Mesh & ms, Vect< real_t > & r, Vect< real_t > & v, Vect< real_t > & p )`

Constructor using mesh and initial data.

Parameters

in	<i>ms</i>	Reference to <code>Mesh</code> instance
in	<i>r</i>	Vector containing initial (elementwise) density
in	<i>v</i>	Vector containing initial (elementwise) velocity
in	<i>p</i>	Vector containing initial (elementwise) pressure

### 7.48.3 Member Function Documentation

`void Forward ( const Vect< real_t > & flux, Vect< real_t > & field )`

Add flux to field.

If this function is used, the user must call `getFlux` himself

Parameters

in	<i>flux</i>	Vector containing fluxes at sides (points)
out	<i>field</i>	Vector containing solution vector

`void getMomentum ( Vect< real_t > & m ) const`

Get vector of momentum at elements.

Parameters

in,out	<i>m</i>	<a href="#">Vect</a> instance that contains on output element momentum
--------	----------	--

**void getInternalEnergy ( Vect< real\_t > & ie ) const**

Get vector of internal energy at elements.

Parameters

in,out	<i>ie</i>	<a href="#">Vect</a> instance that contains on output element internal energy
--------	-----------	---

**void getTotalEnergy ( Vect< real\_t > & te ) const**

Get vector of total energy at elements.

Parameters

in,out	<i>te</i>	<a href="#">Vect</a> instance that contains on output element total energy
--------	-----------	--

**void getSoundSpeed ( Vect< real\_t > & s ) const**

Get vector of sound speed at elements.

Parameters

in,out	<i>s</i>	<a href="#">Vect</a> instance that contains on output element sound speed
--------	----------	---

**void getMach ( Vect< real\_t > & m ) const**

Get vector of elementwise Mach number.

Parameters

in,out	<i>m</i>	<a href="#">Vect</a> instance that contains on output element Mach number
--------	----------	---

**void setInitialCondition ( const LocalVect< real\_t, 3 > & u )**

A constant initial condition.

Parameters

in	<i>u</i>	<a href="#">LocalVect</a> instance containing density, velocity and pressure
----	----------	--

**void setBC ( const Side & sd, real\_t u )**

Assign a boundary condition as a constant to a given side.

Parameters

in	<i>sd</i>	<a href="#">Side</a> to which the value is assigned
in	<i>u</i>	Value to assign

**void setBC ( int code, real\_t a )**

Assign a boundary condition value.

Parameters

in	<i>code</i>	Code value to which boundary condition is assigned
in	<i>a</i>	Value to assign to sides that have code <i>code</i>

**void setBC ( real\_t a )**

Assign a boundary condition value.

Parameters

in	<i>a</i>	Value to assign to all boundary sides
----	----------	---------------------------------------

**void setBC ( const Side & sd, const LocalVect< real\_t, 3 > & u )**

Assign a Dirichlet boundary condition vector.

Parameters

in	<i>sd</i>	<a href="#">Side</a> instance to which the values are assigned
in	<i>u</i>	<a href="#">LocalVect</a> instance that contains values to assign to the side

**void setBC ( int code, const LocalVect< real\_t, 3 > & U )**

Assign a Dirichlet boundary condition vector.

Parameters

in	<i>code</i>	<a href="#">Side</a> code for which the values are assigned
in	<i>U</i>	<a href="#">LocalVect</a> instance that contains values to assign to sides with code <i>code</i>

**void setBC ( const LocalVect< real\_t, 3 > & u )**

Assign a Dirichlet boundary condition vector.

Parameters

in	<i>u</i>	<a href="#">LocalVect</a> instance that contains values to assign to all boundary sides
----	----------	---

**void setInOutflowBC ( const Side & sd, const LocalVect< real\_t, 3 > & u )**

Impose a constant inflow or outflow boundary condition on a given side.

Parameters

in	<i>sd</i>	Instance of <a href="#">Side</a> on which the condition is prescribed
in	<i>u</i>	<a href="#">LocalVect</a> instance that contains values to assign to the side

**void setInOutflowBC ( int code, const LocalVect< real\_t, 3 > & u )**

Impose a constant inflow or outflow boundary condition on sides with a given code.

Parameters

<code>in</code>	<i>code</i>	Value of code for which the condition is prescribed
<code>in</code>	<i>u</i>	<a href="#">LocalVect</a> instance that contains values to assign to the sides

**void setInOutflowBC ( const LocalVect< real\_t, 3 > &u )**

Impose a constant inflow or outflow boundary condition on boundary sides.

Parameters

<code>in</code>	<i>u</i>	<a href="#">LocalVect</a> instance that contains values to assign to the sides
-----------------	----------	--

- `void setBC (real.t u)`  
*Prescribe a constant boundary condition on all boundary sides.*
- `void setBC (const Side &sd, const LocalVect< real.t, 4 > &u)`  
*Prescribe a constant boundary condition at a given side.*
- `void setBC (int code, const LocalVect< real.t, 4 > &u)`  
*Prescribe a constant boundary condition for a given code.*
- `void setBC (const LocalVect< real.t, 4 > &u)`  
*Prescribe a constant boundary condition at all boundary sides.*
- `real.t getR (size_t i)` const  
*Return density at given element label.*
- `real.t getV (size_t i, size_t j)` const
- `real.t getP (size_t i)` const  
*Return pressure at given element label.*

## Additional Inherited Members

### 7.49.1 Detailed Description

Class to solve the Inviscid compressible fluid flows (Euler equations) for perfect gas in 2-D.  
Solution method is a second-order MUSCL Finite Volume scheme on triangles

Author

S. Clain, V. Clauzon

Copyright

GNU Lesser Public License

### 7.49.2 Constructor & Destructor Documentation

**ICPG2DT ( Mesh & *ms*, Vect< real.t > & *r*, Vect< real.t > & *v*, Vect< real.t > & *p* )**

Constructor using mesh and initial data.

Parameters

in	<i>ms</i>	<a href="#">Mesh</a> instance
in	<i>r</i>	Initial density vector (as instance of <a href="#">Vect</a> )
in	<i>v</i>	Initial velocity vector (as instance of <a href="#">Vect</a> )
in	<i>p</i>	Initial pressure vector (as instance of <a href="#">Vect</a> )

### 7.49.3 Member Function Documentation

**void setReconstruction ( )**

Reconstruct.

exit(3) if reconstruction fails

**void Forward ( const Vect< real.t > & *Flux*, Vect< real.t > & *Field* )**

Add Flux to Field.

If this function is used, the function getFlux must be called

**void setSolver ( SolverType *s* )**

Choose solver.

Parameters

in	<i>s</i>	Index of solver in the enumerated variable SolverType Available values are: ROE_SOLVER, VFROE_SOLVER, LF_SOLVER, RUSANOV_SOLVER, HLL_SOLVER, HLLC_SOLVER, MAX_SOLVER
----	----------	--

**void setBC ( const Side & *sd*, real.t *a* )**

Prescribe a constant boundary condition at given side.

Parameters

in	<i>sd</i>	Reference to <a href="#">Side</a> instance
in	<i>a</i>	Value to prescribe

**void setBC ( int *code*, real\_t *a* )**

Prescribe a constant boundary condition for a given code.

Parameters

in	<i>code</i>	Code for which value is imposed
in	<i>a</i>	Value to prescribe

**void setBC ( real\_t *u* )**

Prescribe a constant boundary condition on all boundary sides.

Parameters

in	<i>u</i>	Value to prescribe
----	----------	--------------------

**void setBC ( const Side & *sd*, const LocalVect< real\_t, 4 > & *u* )**

Prescribe a constant boundary condition at a given side.

Parameters

in	<i>sd</i>	Reference to <a href="#">Side</a> instance
in	<i>u</i>	Vector (instance of class <a href="#">LocalVect</a> ) with as components the constant values to prescribe for the four fields ( <i>r</i> , <i>vx</i> , <i>vy</i> , <i>p</i> )

**void setBC ( int *code*, const LocalVect< real\_t, 4 > & *u* )**

Prescribe a constant boundary condition for a given code.

Parameters

in	<i>code</i>	Code for which value is imposed
in	<i>u</i>	Vector (instance of class <a href="#">LocalVect</a> ) with as components the constant values to prescribe for the four fields ( <i>r</i> , <i>vx</i> , <i>vy</i> , <i>p</i> )

**void setBC ( const LocalVect< real\_t, 4 > & *u* )**

Prescribe a constant boundary condition at all boundary sides.

Parameters

in	<i>u</i>	Vector (instance of class <a href="#">LocalVect</a> ) with as components the constant values to prescribe for the four fields ( <i>r</i> , <i>vx</i> , <i>vy</i> , <i>p</i> )
----	----------	---

**real\_t getR ( size\_t *i* ) const**

Return density at given element label.

Parameters

<code>in</code>	<code>i</code>	<a href="#">Element</a> label
-----------------	----------------	-------------------------------

**`real.t getV ( size.t i, size.t j ) const`**

Return velocity at given element label

Parameters

<code>in</code>	<code>i</code>	<a href="#">Element</a> label
<code>in</code>	<code>j</code>	component index (1 or 2)

**`real.t getP ( size.t i ) const`**

Return pressure at given element label.

Parameters

<code>in</code>	<code>i</code>	<a href="#">Element</a> label
-----------------	----------------	-------------------------------

## 7.50 ICPG3DT Class Reference

Class to solve the Inviscid compressible fluid flows (Euler equations) for perfect gas in 3-D.

### 7.51.2 Constructor & Destructor Documentation

**Integration** ( *real.t low*, *real.t high*, *function*< *real.t*(*real.t*)> *const &f*, *IntegrationScheme s*, *real.t error* )

Constructor.

Parameters

<i>in</i>	<i>low</i>	Lower value of integration interval
<i>in</i>	<i>high</i>	Upper value of integration interval
<i>in</i>	<i>f</i>	Function to integrate
<i>in</i>	<i>s</i>	<a href="#">Integration</a> scheme. To choose among enumerated values: <ul style="list-style-type: none"> <li>• LEFT_RECTANGLE:</li> <li>• RIGHT_RECTANGLE:</li> <li>• MID_RECTANGLE:</li> <li>• TRAPEZOIDAL:</li> <li>• SIMPSON:</li> <li>• GAUSS_LEGENDRE:</li> </ul>
<i>in</i>	<i>error</i>	

### 7.51.3 Member Function Documentation

**void setFunction** ( *function*< *real.t*(*real.t*)> *const &f* )

Define function to integrate numerically.

Parameters

<i>in</i>	<i>f</i>	Function to integrate
-----------	----------	-----------------------

**void setScheme** ( *IntegrationScheme s* )

Set time integration scheme.

Parameters

in	s	Scheme to choose among enumerated values: <ul style="list-style-type: none"> <li>• LEFT_RECTANGLE:</li> <li>• RIGHT_RECTANGLE:</li> <li>• MID_RECTANGLE:</li> <li>• TRAPEZOIDAL:</li> <li>• SIMPSON:</li> <li>• GAUSS_LEGENDRE:</li> </ul>
----	---	--

**void setTriangle ( real\_t x1, real\_t y1, real\_t x2, real\_t y2, real\_t x3, real\_t y3 )**

Define integration domain as a quadrilateral.

Parameters

in	x1	x-coordinate of first vertex of triangle
in	y1	y-coordinate of first vertex of triangle
in	x2	x-coordinate of second vertex of triangle
in	y2	y-coordinate of second vertex of triangle
in	x3	x-coordinate of third vertex of triangle
in	y3	y-coordinate of third vertex of triangle

**void setQuadrilateral ( real\_t x1, real\_t y1, real\_t x2, real\_t y2, real\_t x3, real\_t y3, real\_t x4, real\_t y4 )**

Define integration domain as a quadrilateral.

Parameters

in	x1	x-coordinate of first vertex of quadrilateral
in	y1	y-coordinate of first vertex of quadrilateral
in	x2	x-coordinate of second vertex of quadrilateral
in	y2	y-coordinate of second vertex of quadrilateral
in	x3	x-coordinate of third vertex of quadrilateral
in	y3	y-coordinate of third vertex of quadrilateral
in	x4	x-coordinate of fourth vertex of quadrilateral
in	y4	y-coordinate of fourth vertex of quadrilateral

**real\_t run ( )**

Run numerical integration.

Returns

Computed approximate value of integral

## 7.52 IOField Class Reference

Enables working with files in the XML Format.

Inherits XMLParser.

## Public Types

- enum [AccessType](#)  
*Enumerated values for file access type.*

## Public Member Functions

- [IOField](#) ()  
*Default constructor.*

## 7.53 IPF Class Reference

To read project parameters from a file in [IPF](#) format.

### Public Member Functions

- [IPF](#) ()  
*Default constructor.*
- [IPF](#) (const string &file)  
*Constructor that gives the data file name.*
- [IPF](#) (const string &prog, const string &file)  
*Constructor that reads parameters in file *file* and prints header information for the calling program *prog*. It reads parameters in [IPF](#) Format from this file.*
- [~IPF](#) ()  
*Destructor.*
- [real\\_t](#) [getDisplay](#) ()  
*Display acquired parameters.*
- [int](#) [getVerbose](#) ()  
*Return parameter read using keyword **Verbose**.*
- [int](#) [getOutput](#) () const  
*Return parameter read using keyword **Output**.*
- [int](#) [getSave](#) () const  
*Return parameter read using keyword **Save**.*
- [int](#) [getPlot](#) () const  
*Return parameter read using keyword **Plot**.*
- [int](#) [getBC](#) () const  
*Return parameter read using keyword **BC**.*
- [int](#) [getBF](#) () const  
*Return parameter read using keyword **BF**.*
- [int](#) [getSF](#) () const  
*Return parameter read using keyword **SF**.*
- [int](#) [getInit](#) () const  
*Return parameter read using keyword **Init**.*
- [int](#) [getData](#) () const  
*Return parameter read using keyword **Data**.*
- [size\\_t](#) [getNbSteps](#) () const  
*Return parameter read using keyword **NbSteps**.*

- `size_t getNbIter ()` const  
Return parameter read using keyword *NbIter*.
- `real_t getTimeStep ()` const  
Return parameter read using keyword *TimeStep*.
- `real_t getMaxTime ()` const  
Return parameter read using keyword *MaxTime*.
- `real_t getTolerance ()` const  
Return parameter read using keyword *Tolerance*.
- `int getIntPar (size_t n=1)` const  
Return *n*-th parameter read using keyword *IntPar*.
- `string getStringPar (size_t n=1)` const  
Return *n*-th parameter read using keyword *StringPar*.
- `real_t getDoublePar (size_t n=1)` const  
Return *n*-th parameter read using keyword *DoublePar*.
- `Point< real_t > getPointDoublePar (size_t n=1)` const  
Return *n*-th parameter read using keyword *PointDoublePar*.
- `complex_t getComplexPar (size_t n=1)` const  
Return *n*-th parameter read using keyword *StringPar*.
- `string getString (const string &label)` const  
Return parameter corresponding to a given label, when its value is a string.
- `string getString (const string &label, string def)` const  
Return parameter corresponding to a given label, when its value is a string.
- `int getInteger (const string &label)` const  
Return parameter corresponding to a given label, when its value is an integer.
- `int getInteger (const string &label, int def)` const  
Return parameter corresponding to a given label, when its value is an integer.
- `real_t getDouble (const string &label)` const  
Return parameter corresponding to a given label, when its value is a *real\_t*.
- `real_t getDouble (const string &label, real_t def)` const  
Return parameter corresponding to a given label, when its value is a *real\_t*.
- `complex_t getComplex (const string &label)` const  
Return parameter corresponding to a given label, when its value is a complex number.
- `complex_t getComplex (const string &label, complex_t def)` const  
Return parameter corresponding to a given label, when its value is a complex number.
- `int contains (const string &label)` const  
check if the project file contains a given parameter
- `void get (const string &label, Vect< real_t > &a)` const  
Read an array of real values, corresponding to a given label.
- `real_t getArraySize (const string &label, size_t j)` const  
Return an array entry for a given label.
- `void get (const string &label, int &a)` const  
Return integer parameter corresponding to a given label.
- `void get (const string &label, real_t &a)` const  
Return real parameter corresponding to a given label.
- `void get (const string &label, complex_t &a)` const  
Return complex parameter corresponding to a given label.

- void `get` (const string &label, string &a) const  
Return string parameter corresponding to a given label.
- string `getProject` () const  
Return parameter read using keyword **Project**.
- string `getDomainFile` () const  
Return parameter using keyword **Mesh**.
- string `getMeshFile` (size\_t i=1) const  
Return *i*-th parameter read using keyword **mesh\_file**.
- string `getInitFile` () const  
Return parameter read using keyword **InitFile**.
- string `getRestartFile` () const  
Return parameter read using keyword **RestartFile**.
- string `getBCFile` () const  
Return parameter read using keyword **BCFile**.
- string `getBFFile` () const  
Return parameter read using keyword **BFFile**.
- string `getSFFile` () const  
Return parameter read using keyword **SFFile**.
- string `getSaveFile` () const  
Return parameter read using keyword **SaveFile**.
- string `getPlotFile` (int i=1) const  
Return *i*-th parameter read using keyword **PlotFile**.
- string `getPrescriptionFile` (int i=1) const  
Return parameter read using keyword **DataFile**.
- string `getAuxFile` (size\_t i=1) const  
Return *i*-th parameter read using keyword **Auxfile**.
- string `getDensity` () const  
Return expression (to be parsed, function of *x*, *y*, *z*, *t*) for density function.
- string `getElectricConductivity` () const  
Return expression (to be parsed, function of *x*, *y*, *z*, *t*) for electric conductivity.
- string `getElectricPermittivity` () const  
Return expression (to be parsed, function of *x*, *y*, *z*, *t*) for electric permittivity.
- string `getMagneticPermeability` () const  
Return expression (to be parsed, function of *x*, *y*, *z*, *t*) for magnetic permeability.
- string `getPoissonRatio` () const  
Return expression (to be parsed, function of *x*, *y*, *z*, *t*) for Poisson ratio.
- string `getThermalConductivity` () const  
Return expression (to be parsed, function of *x*, *y*, *z*, *t*) for thermal conductivity.
- string `getRhoCp` () const  
Return expression (to be parsed, function of *x*, *y*, *z*, *t*) for density \* specific heat.
- string `getViscosity` () const  
Return expression (to be parsed, function of *x*, *y*, *z*, *t*) for viscosity.
- string `getYoungModulus` () const  
Return expression (to be parsed, function of *x*, *y*, *z*, *t*) for Young's modulus.

### 7.53.1 Detailed Description

To read project parameters from a file in [IPF](#) format.

This class can be used to acquire various parameters from a parameter file of [IPF](#) (Input Project File). The declaration of an instance of this class avoids reading data in your main program. The acquired parameters are retrieved through information members of the class. Note that all the parameters have default values

GNU Lesser Public License

### 7.53.2 Constructor & Destructor Documentation

**IPF ( const string & *file* )**

Constructor that gives the data file name.

It reads parameters in [IPF](#) Format from this file.

### 7.53.3 Member Function Documentation

**int getOutput ( ) const**

Return parameter read using keyword **Output**.

This parameter can be used to control output behavior in a program.

**int getSave ( ) const**

Return parameter read using keyword **Save**.

This parameter can be used to control result saving in a program (*e.g.* for a restarting purpose).

**int getPlot ( ) const**

Return parameter read using keyword **Plot**.

This parameter can be used to control result saving for plotting in a program.

**int getBC ( ) const**

Return parameter read using keyword **BC**.

This parameter can be used to set a boundary condition flag.

**int getBF ( ) const**

Return parameter read using keyword **BF**.

This parameter can be used to set a body force flag.

**int getSF ( ) const**

Return parameter read using keyword **SF**.

This parameter can be used to set a surface force flag.

**int getInit ( ) const**

Return parameter read using keyword **Init**.

This parameter can be used to set an initial data flag.

**int getData ( ) const**

Return parameter read using keyword **Data**.

This parameter can be used to set a various data flag.

**size\_t getNbSteps ( ) const**

Return parameter read using keyword **NbSteps**.

This parameter can be used to read a number of time steps.

**size\_t getNbIter ( ) const**

Return parameter read using keyword **NbIter**.

This parameter can be used to read a number of iterations.

**real\_t getTimeStep ( ) const**

Return parameter read using keyword **TimeStep**.

This parameter can be used to read a time step value.

**real\_t getMaxTime ( ) const**

Return parameter read using keyword **MaxTime**.

This parameter can be used to read a maximum time value.

**real\_t getTolerance ( ) const**

Return parameter read using keyword **Tolerance**.

This parameter can be used to read a tolerance value to control convergence.

**int getIntPar ( size\_t n = 1 ) const**

Return  $n$ -th parameter read using keyword **IntPar**

Here we have at most 20 integer extra parameters that can be used for any purpose. Default value for  $n$  is 1

**string getStringPar ( size\_t n = 1 ) const**

Return  $n$ -th parameter read using keyword **StringPar**.

Here we have at most 20 integer extra parameters that can be used for any purpose. Default value for  $n$  is 1

**real\_t getDoublePar ( size\_t n = 1 ) const**

Return  $n$ -th parameter read using keyword **DoublePar**.

Here we have at most 20 integer extra parameters that can be used for any purpose. Default value for  $n$  is 1

**Point<real\_t> getPointDoublePar ( size\_t n = 1 ) const**

Return n-th parameter read using keyword **PointDoublePar**.

Here we have at most 20 integer extra parameters that can be used for any purpose. Default value for n is 1

**complex\_t getComplexPar ( size\_t n = 1 ) const**

Return n-th parameter read using keyword **StringPar**.

Here we have at most 20 integer extra parameters that can be used for any purpose. Default value for n is 1

**string getString ( const string & label ) const**

Return parameter corresponding to a given label, when its value is a string.

Parameters

<b>in</b>	<i>label</i>	Label that identifies the string (read from input file) If this label is not found an error message is displayed and program stops
-----------	--------------	--

**string getString ( const string & label, string def ) const**

Return parameter corresponding to a given label, when its value is a string.

Case where a default value is provided

Parameters

<b>in</b>	<i>label</i>	Label that identifies the string (read from input file)
<b>in</b>	<i>def</i>	Default value: Value to assign if the sought parameter is not found

**int getInteger ( const string & label ) const**

Return parameter corresponding to a given label, when its value is an integer.

Parameters

<b>in</b>	<i>label</i>	Label that identifies the integer number (read from input file) If this label is not found an error message is displayed and program stops
-----------	--------------	--

**int getInteger ( const string & label, int def ) const**

Return parameter corresponding to a given label, when its value is an integer.

Case where a default value is provided

Parameters

<b>in</b>	<i>label</i>	Label that identifies the integer number (read from input file).
<b>in</b>	<i>def</i>	Default value: Value to assign if the sought parameter is not found

**real\_t getDouble ( const string & label ) const**

Return parameter corresponding to a given label, when its value is a real\_t.

Parameters

<b>in</b>	<i>label</i>	Label that identifies the real number (read from input file). If this label is not found an error message is displayed and program stops.
-----------	--------------	---

**real\_t getDouble ( const string & label, real\_t def ) const**

Return parameter corresponding to a given label, when its value is a real\_t.

Case where a default value is provided

Parameters

<b>in</b>	<i>label</i>	Label that identifies the real number (read from input file)
<b>in</b>	<i>def</i>	Default value: Value to assign if the sought parameter is not found

**complex\_t getComplex ( const string & label ) const**

Return parameter corresponding to a given label, when its value is a complex number.

Parameters

<b>in</b>	<i>label</i>	Label that identifies the complex number (read from input file) If this label is not found an error message is displayed and program stops
-----------	--------------	--

**complex\_t getComplex ( const string & label, complex\_t def ) const**

Return parameter corresponding to a given label, when its value is a complex number.

Case where a default value is provided

Parameters

<b>in</b>	<i>label</i>	Label that identifies the complex number (read from input file)
<b>in</b>	<i>def</i>	Default value: Value to assign if the sought parameter is not found

**int contains ( const string & label ) const**

check if the project file contains a given parameter

Parameters

<b>in</b>	<i>label</i>	Label that identifies the label to seek in file
-----------	--------------	---

Returns

0 if the parameter is not found, n if the parameter is found, where n is the parameter index in the parameter list

**void get ( const string & label, Vect< real\_t > & a ) const**

Read an array of real values, corresponding to a given label.

## Parameters

in	<i>label</i>	Label that identifies the array (read from input file).
in	<i>a</i>	Vector that contain the array. The vector is properly resized before filling.

## Remarks

If this label is not found an error message is displayed.

**real\_t getArraySize ( const string & *label*, size\_t *j* ) const**

Return an array entry for a given label.

## Parameters

in	<i>label</i>	Label that identifies the array (read from input file).
in	<i>j</i>	Index of entry in the array (Starting from 1)

## Remarks

If this label is not found an error message is displayed and program stops.

**void get ( const string & *label*, int & *a* ) const**

Return integer parameter corresponding to a given label.

## Parameters

in	<i>label</i>	Label that identifies the integer number (read from input file).
out	<i>a</i>	Returned value. If this label is not found an error message is displayed and program stops. Note: This member function can be used instead of getInteger

**void get ( const string & *label*, real\_t & *a* ) const**

Return real parameter corresponding to a given label.

## Parameters

in	<i>label</i>	Label that identifies the real (real_t) number (read from input file).
out	<i>a</i>	Returned value. If this label is not found an error message is displayed and program stops. Note: This member function can be used instead of getReal_T

**void get ( const string & *label*, complex\_t & *a* ) const**

Return complex parameter corresponding to a given label.

## Parameters

in	<i>label</i>	Label that identifies the complex number (read from input file).
out	<i>a</i>	Returned value. If this label is not found an error message is displayed and program stops.

**void get ( const string & *label*, string & *a* ) const**

Return string parameter corresponding to a given label.

## Parameters

<b>in</b>	<i>label</i>	Label that identifies the atring (read from input file).
<b>out</b>	<i>a</i>	Returned value. Note: This member function can be used instead of getString If this label is not found an error message is displayed and program stops. Note: This member function can be used instead of getString

**string getProject ( ) const**

Return parameter read using keyword **Project**.  
This parameter can be used to read a project's name.

**string getMeshFile ( size\_t i = 1 ) const**

Return i-th parameter read using keyword **mesh\_file**.  
Here we have at most 10 integer extra parameters that can be used for any purpose. Default value for i is 1

**string getInitFile ( ) const**

Return parameter read using keyword **InitFile**.  
This parameter can be used to read an initial data file name.

**string getRestartFile ( ) const**

Return parameter read using keyword **RestartFile**.  
This parameter can be used to read a restart file name.

**string getBCFile ( ) const**

Return parameter read using keyword **BCFile**.  
This parameter can be used to read a boundary condition file name.

**string getBFFile ( ) const**

Return parameter read using keyword **BFFile**.  
This parameter can be used to read a body force file name.

**string getSFFile ( ) const**

Return parameter read using keyword **SFFile**.  
This parameter can be used to read a source force file name.

**string getSaveFile ( ) const**

Return parameter read using keyword **SaveFile**.  
This parameter can be used to read a save file name.

**string getPlotFile ( int i = 1 ) const**

Return i-th parameter read using keyword **PlotFile**.  
Here we have at most 10 integer extra parameters that can be used for plot file names. Default value for i is 1

**string getPrescriptionFile ( int *i* = 1 ) const**

Return parameter read using keyword **DataFile**.

This parameter can be used to read a [Prescription](#) file.

**string getAuxFile ( size\_t *i* = 1 ) const**

Return *i*-th parameter read using keyword **Auxfile**.

Here we have at most 10 integer extra parameters that can be used for any auxiliary file names.  
Default value for *i* is 1

## 7.54 Iter< T\_ > Class Template Reference

Class to drive an iterative process.

### Public Member Functions

### 7.54.1 Detailed Description

**template<class T\_>class OFELI::Iter< T\_ >**

Class to drive an iterative process.

This template class enables monitoring any iterative process. It simply sets default values for tolerance, maximal number of iterations and enables checking convergence using two successive iterates.

Rachid Touzani

Copyright

GNU Lesser Public License

### 7.54.2 Member Function Documentation

**void setMaxIter ( int *max\_it* )**

Set maximal number of iterations.

Parameters

<b>in</b>	<i>max_it</i>	Maximal number of iterations [Default: 100]
-----------	---------------	---

**void setTolerance ( real.t toler )**

Set tolerance value for convergence.

Parameters

<b>in</b>	<i>toler</i>	Tolerance value [Default: 1.e-8]
-----------	--------------	----------------------------------

**void setVerbose ( int v )**

Set verbosity parameter.

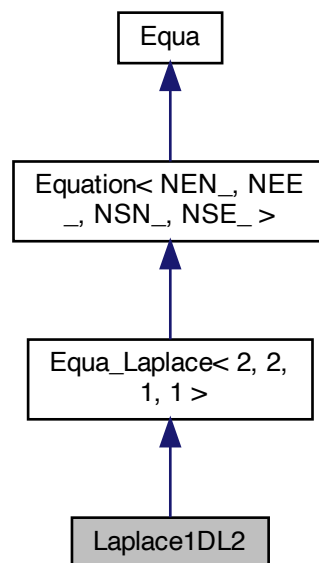

Parameters

<b>in</b>	<i>v</i>	Verbosity parameter [Default: 0]
-----------	----------	----------------------------------

### 7.55.2 Constructor & Destructor Documentation

**Laplace1DL2 ( Mesh & *ms*, Vect< real.t > & *u* )**

Constructor using mesh instance and solution vector

Parameters

in	<i>ms</i>	<a href="#">Mesh</a> instance
in,out	<i>u</i>	<a href="#">Vect</a> instance that contains, after execution of <b>run()</b> the solution

**Laplace1DL2 ( Mesh & *ms* )**

Constructor using mesh instance

Parameters

in	<i>ms</i>	<a href="#">Mesh</a> instance
----	-----------	-------------------------------

### 7.55.3 Member Function Documentation

**void buildEigen ( int *opt* = 0 ) [virtual]**

Build global stiffness and mass matrices for the eigen system.

Parameters

in	<i>opt</i>	Flag to choose a lumped mass matrix (0) or consistent (1) [Default: 0]
----	------------	---

Reimplemented from [Equa.Laplace< 2, 2, 1, 1 >](#).

**void BodyRHS ( const Vect< real.t > & *f* ) [virtual]**

Add Right-Hand Side Contribution.

Parameters

in	<i>f</i>	Vector containing the source given function at mesh nodes
----	----------	---

Reimplemented from [Equa.Laplace< 2, 2, 1, 1 >](#).

**void BoundaryRHS ( const Vect< real.t > & *f* ) [virtual]**

Add Neumann contribution to Right-Hand Side.

Parameters

<code>in</code>	<code>f</code>	Vector with size the total number of nodes. The first entry stands for the force at the first node (Neumann condition) and the last entry is the force at the last node (Neumann condition)
-----------------	----------------	---

Reimplemented from [Equa.Laplace< 2, 2, 1, 1 >](#).

**void setBoundaryCondition ( real\_t *f*, int *lr* )**

Set Dirichlet boundary data.

Parameters

<code>in</code>	<code>f</code>	Value to assign
<code>in</code>	<code>lr</code>	Option to choose location of the value (-1: Left end, 1: Right end)

**void setTraction ( real\_t *f*, int *lr* )**

Set Traction data.

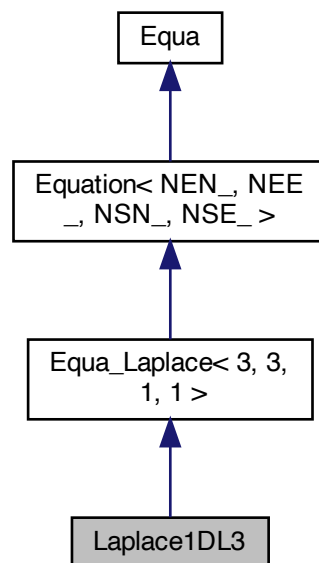

Parameters

<code>in</code>	<code>f</code>	Value of traction (Neumann boundary condition)
<code>in</code>	<code>lr</code>	Option to choose location of the traction (-1: Left end, 1: Right end)

Constructor using mesh instance.

Parameters

<i>in</i>	<i>ms</i>	<a href="#">Mesh</a> instance
-----------	-----------	-------------------------------

### Laplace1DL3 ( Mesh & *ms*, Vect< real.t > & *u* )

Constructor using mesh instance and solution vector

Parameters

<i>in</i>	<i>ms</i>	<a href="#">Mesh</a> instance
<i>in</i> , <i>out</i>	<i>u</i>	<a href="#">Vect</a> instance that contains, after execution of <b>run()</b> the solution

## 7.56.3 Member Function Documentation

### void BodyRHS ( const Vect< real.t > & *f* ) [virtual]

Add Right-hand side contribution.

Parameters

<i>in</i>	<i>f</i>	Vector of right-hand side of the Poisson equation at nodes
-----------	----------	--

Reimplemented from [Equa.Laplace< 3, 3, 1, 1 >](#).

### void BoundaryRHS ( const Vect< real.t > & *h* ) [virtual]

Add Neumann contribution to Right-Hand Side.

Parameters

<i>in</i>	<i>h</i>	Vector with size the total number of nodes. The first entry stands for the force at the first node (Neumann condition) and the last entry is the force at the last node (Neumann condition)
-----------	----------	---

Reimplemented from [Equa.Laplace< 3, 3, 1, 1 >](#).

### void setTraction ( real.t *f*, int *lr* )

Set Traction data.

Parameters

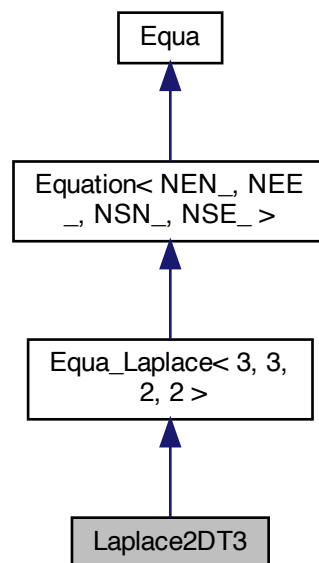

<i>in</i>	<i>f</i>	Value of traction (Neumann boundary condition)
-----------	----------	--

<code>in</code>	<code>lr</code>	Option to choose location of the traction (-1: Left end, 1: Right end)
-----------------	-----------------	--

### 7.57.2 Constructor & Destructor Documentation

#### Laplace2DT3 ( Mesh & *ms* )

Constructor with mesh.

Parameters

in	<i>ms</i>	<a href="#">Mesh</a> instance
----	-----------	-------------------------------

#### Laplace2DT3 ( Mesh & *ms*, Vect< real.t > & *u* )

Constructor using mesh and solution vector.

Parameters

in	<i>ms</i>	<a href="#">Mesh</a> instance
in	<i>u</i>	Problem right-hand side

#### Laplace2DT3 ( Mesh & *ms*, Vect< real.t > & *b*, Vect< real.t > & *Dbc*, Vect< real.t > & *Nbc*, Vect< real.t > & *u* )

Constructor that initializes a standard Poisson equation.

This constructor sets data for the Poisson equation with mixed (Dirichlet and Neumann) boundary conditions.

Parameters

in	<i>ms</i>	<a href="#">Mesh</a> instance
in	<i>b</i>	Vector containing the source term (right-hand side of the equation) at mesh nodes
in	<i>Dbc</i>	Vector containing prescribed values of the solution (Dirichlet boundary condition) at nodes with positive code. Its size is the total number of nodes
in	<i>Nbc</i>	Vector containing prescribed fluxes (Neumann boundary conditions) at sides, its size is the total number of sides
in	<i>u</i>	Vector to contain the finite element solution at nodes once the member function run() is called.

### 7.57.3 Member Function Documentation

**void BodyRHS ( const Vect< real.t > & *f* )** [virtual]

Add body source term to right-hand side.

Parameters

<b>in</b>	$f$	Vector containing the source given function at mesh nodes
-----------	-----	---

Reimplemented from [Equa.Laplace< 3, 3, 2, 2 >](#).

**void BoundaryRHS ( const Vect< real\_t > &h ) [virtual]**

Add boundary source term to right-hand side.

Parameters

<b>in</b>	$h$	Vector containing the source given function at mesh nodes
-----------	-----	---

Reimplemented from [Equa.Laplace< 3, 3, 2, 2 >](#).

**void buildEigen ( int opt = 0 ) [virtual]**

Build global stiffness and mass matrices for the eigen system.

Parameters

<b>in</b>	$opt$	Flag to choose a lumped mass matrix (0) or consistent (1) [Default: 0]
-----------	-------	--

Reimplemented from [Equa.Laplace< 3, 3, 2, 2 >](#).

**void Post ( const Vect< real\_t > &u, Vect< Point< real\_t > > &p )**

Perform post calculations.

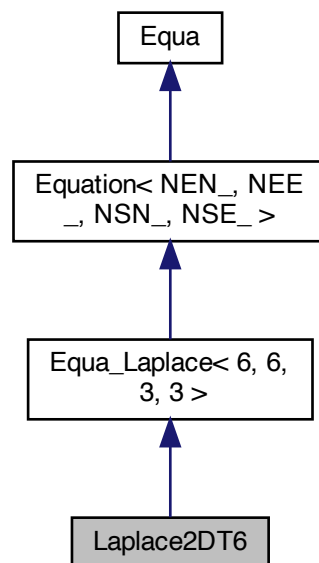

Parameters

<b>in</b>	$u$	Solution at nodes
<b>out</b>	$p$	Vector containing gradient at elements

### 7.59.1 Detailed Description

To build and solve the linear system for the Poisson problem using the [DG](#)  $P_1$  2-D triangle element.

This class build the linear system of equations for a standard elliptic equation using the Discontinuous Galerkin  $P_1$  finite element method.

Author

Rachid Touzani

Copyright

GNU Lesser Public License

### 7.59.2 Constructor & Destructor Documentation

**LaplaceDG2DP1** ( *Mesh* & *ms*, *Vect*< *real.t* > & *f*, *Vect*< *real.t* > & *Dbc*, *Vect*< *real.t* > & *Nbc*, *Vect*< *real.t* > & *u* )

Constructor with mesh and vector data.

Parameters

in	<i>ms</i>	<a href="#">Mesh</a> instance
in	<i>f</i>	Vector containing the right-hand side of the elliptic equation at triangle vertices
in	<i>Dbc</i>	Vector containing prescribed values of the solution (Dirichlet boundary condition) at nodes having a positive code
in	<i>Nbc</i>	Vector containing prescribed values of the flux (Neumann boundary condition) at each side having a positive code
in	<i>u</i>	Vector where the solution is stored once the linear system is solved

### 7.59.3 Member Function Documentation

**void set** ( *real.t* *sigma*, *real.t* *eps* )

Set parameters for the [DG](#) method.

Parameters

in	<i>sigma</i>	Penalty parameters to enforce continuity at nodes (Must be positive) [Default: 100]
in	<i>eps</i>	<p>Epsilon value of the <a href="#">DG</a> method to choose among the values:</p> <ul style="list-style-type: none"> <li>• 0 Incomplete Interior Penalty Galerkin method (IIPG)</li> <li>• -1 Symmetric Interior Penalty Galerkin method (SIPG)</li> <li>• 1 Non symmetric interior penalty Galerkin method (NIPG)</li> </ul> <p>For a user not familiar with the method, please choose the value of <i>eps</i>=-1 and <i>sigma</i>&gt;100 which leads to a symmetric positive definite matrix [Default: -1]</p>

**void set** ( *const LocalMatrix*< *real.t*, 2, 2 > & *K* )

Set diffusivity matrix.

This function provides the diffusivity matrix as instance of class [LocalMatrix](#). The default diffusivity matrix is the identity matrix

Parameters

<code>in</code>	<code>K</code>	Diffusivity matrix
-----------------	----------------	--------------------

### **void build ( )**

Build global matrix and right-hand side.

The problem matrix and right-hand side are the ones used in the constructor. They are updated in this member function.

### **void Smooth ( Vect< real.t > &u )**

Perform post calculations.

This function gives an averaged solution given at mesh nodes (triangle vertices) by a standard  $L_2$ -projection method.

Parameters

<code>in</code>	<code>u</code>	Solution at nodes
-----------------	----------------	-------------------

### **int run ( )**

Build and solve the linear system of equations using an iterative method.

The matrix is preconditioned by the diagonal ILU method. The linear system is solved either by the Conjugate Gradient method if the matrix is symmetric positive definite (`eps=-1`) or the GMRES method if not. The solution is stored in the vector `u` given in the constructor.

Returns

Number of performed iterations. Note that the maximal number is 1000 and the tolerance is  $1.e-8$

## **7.60 LCL1D Class Reference**

## Additional Inherited Members

### 7.60.1 Detailed Description

Class to solve the linear conservation law (Hyperbolic equation) in 1-D by a MUSCL Finite Volume scheme.

Author

S. Clain, V. Clauzon

Copyright

GNU Lesser Public License

### 7.60.2 Member Function Documentation

**void setInitialCondition ( Vect< real.t > & u )**

Assign initial condition by a vector.

Parameters

<code>in</code>	<code>u</code>	Vector containing initial condition
-----------------	----------------	-------------------------------------

**void setInitialCondition ( `real_t u` )**

Assign a constant initial condition.

Parameters

<code>in</code>	<code>u</code>	Constant value for the initial condition
-----------------	----------------	--

**real\_t runOneTimeStep ( )**

Run one time step of the linear conservation law.

Returns

Value of the time step

**void setBC ( `real_t u` )**

Set Dirichlet boundary condition.

Assign a constant value `u` to all boundary sides

**void setBC ( `const Side & sd`, `real_t u` )**

Set Dirichlet boundary condition.

Assign a constant value to a side

Parameters

<code>in</code>	<code>sd</code>	<a href="#">Side</a> to which value is prescribed
<code>in</code>	<code>u</code>	Value to prescribe

**void setBC ( `int code`, `real_t u` )**

Set Dirichlet boundary condition.

Assign a constant value sides with a given code

Parameters

<code>in</code>	<code>code</code>	Code of sides to which value is prescribed
<code>in</code>	<code>u</code>	Value to prescribe

**void setVelocity ( `Vect< real_t > & v` )**

Set convection velocity.

Parameters

<code>in</code>	<code>v</code>	<a href="#">Vect</a> instance containing velocity
-----------------	----------------	---

**void Forward ( const Vect< real\_t > & Flux, Vect< real\_t > & Field )**

Computation of the primal variable  $n \rightarrow n+1$ .

Vector **Flux** contains elementwise fluxes issued from the Riemann problem, calculated with, as left element, **getNeighborElement(1)** and right element **getNeighborElement(2)** if **getNeighborElement(2)** doesn't exist, we are on a boundary and we prescribe a symmetry condition

### 7.61.1 Detailed Description

Class to solve the linear hyperbolic equation in 2-D by a MUSCL Finite Volume scheme on triangles.

Author

S. Clain, V. Clauzon

Copyright

GNU Lesser Public License

### 7.61.2 Constructor & Destructor Documentation

[LCL2DT](#) ( [Mesh](#) & m, [Vect](#)< [real.t](#) > & U )

Constructor using mesh and initial data.

Parameters

<code>in</code>	$m$	Reference to <a href="#">Mesh</a> instance
<code>in</code>	$U$	Vector containing initial (elementwise) solution

### 7.61.3 Member Function Documentation

**void setInitialCondition ( Vect< real\_t > &  $u$  )**

Set elementwise initial condition.

Parameters

<code>in</code>	$u$	<a href="#">Vect</a> instance containing initial condition values
-----------------	-----	---

**void setInitialCondition ( real\_t  $u$  )**

Set a constant initial condition.

Parameters

<code>in</code>	$u$	Value of initial condition to assign to all elements
-----------------	-----	--

**real\_t runOneTimeStep ( )**

Run one time step of the linear conservation law.

Returns

Value of the time step

**void setBC ( real\_t  $u$  )**

Set Dirichlet boundary condition.

Assign a constant value  $u$  to all boundary sides

**void setBC ( const Side &  $sd$ , real\_t  $u$  )**

Set Dirichlet boundary condition.

Assign a constant value to a side

Parameters

<code>in</code>	$sd$	<a href="#">Side</a> to which value is prescribed
<code>in</code>	$u$	Value to prescribe

**void setBC ( int  $code$ , real\_t  $u$  )**

Set Dirichlet boundary condition.

Assign a constant value sides with a given code

Parameters

<code>in</code>	$code$	Code of sides to which value is prescribed
-----------------	--------	--

<code>in</code>	<code>u</code>	Value to prescribe
-----------------	----------------	--------------------

**void setVelocity ( const Vect< real.t > & v )**

Set convection velocity.

Parameters

<code>in</code>	<code>v</code>	<a href="#">Vect</a> instance containing velocity
-----------------	----------------	---

**void setVelocity ( const LocalVect< real.t, 2 > & v )**

Set (constant) convection velocity.

Parameters

<code>in</code>	<code>v</code>	Vector containing constant velocity to prescribe
-----------------	----------------	--

**void Forward ( const Vect< real.t > & Flux, Vect< real.t > & Field )**

Computation of the primal variable  $n \rightarrow n+1$ .

Vector *Flux* contains elementwise fluxes issued from the Riemann problem, calculated with, as left element, **getNeighborElement(1)** and right element **getNeighborElement(2)** if **getNeighborElement(2)** doesn't exist, we are on a boundary and we prescribe a symmetry condition

### 7.62.2 Constructor & Destructor Documentation

**LCL3DT ( Mesh &  $m$ , Vect< real\_t > &  $U$  )**

Constructor using mesh and initial field.

Parameters

in	$m$	Reference to <a href="#">Mesh</a> instance
in	$U$	Vector containing initial (elementwise) solution

### 7.62.3 Member Function Documentation

**void setInitialCondition ( Vect< real\_t > &  $u$  )**

Set elementwise initial condition.

Parameters

in	$u$	<a href="#">Vect</a> instance containing initial condition values
----	-----	---

**void setInitialCondition ( real\_t  $u$  )**

Set a constant initial condition.

Parameters

in	$u$	Value of initial condition to assign to all elements
----	-----	--

**void setBC ( const Side &  $sd$ , real\_t  $u$  )**

Set Dirichlet boundary condition.

Assign a constant value to a side

Parameters

<code>in</code>	<code>sd</code>	<a href="#">Side</a> to which value is prescribed
<code>in</code>	<code>u</code>	Value to prescribe

**void setBC ( int *code*, real\_t *u* )**

Set Dirichlet boundary condition.

Assign a constant value sides with a given code

Parameters

<code>in</code>	<code>code</code>	Code of sides to which value is prescribed
<code>in</code>	<code>u</code>	Value to prescribe

**void setVelocity ( const Vect< real\_t > & *v* )**

Set convection velocity.

Parameters

<code>in</code>	<code>v</code>	<a href="#">Vect</a> instance containing velocity
-----------------	----------------	---

**void setVelocity ( const LocalVect< real\_t, 3 > & *v* )**

Set (constant) convection velocity.

Parameters

<code>in</code>	<code>v</code>	Vector containing constant velocity to prescribe
-----------------	----------------	--

**void Forward ( const Vect< real\_t > & *Flux*, Vect< real\_t > & *Field* )**

Computation of the primal variable  $n \rightarrow n+1$ .

Vector *Flux* contains elementwise fluxes issued from the Riemann problem, calculated with, as left element, **getNeighborElement(1)** and right element **getNeighborElement(2)** if **getNeighborElement(2)** doesn't exist, we are on a boundary and we prescribe a symmetry condition

### 7.63.1 Detailed Description

To describe a 2-Node planar line finite element.

Defines geometric quantities associated to 2-node linear segment element  $P_1$  in the space. The reference element is the segment  $[-1, 1]$ . Note that the line length is not checked unless the function check is called.

Author

Rachid Touzani

Copyright

GNU Lesser Public License

### 7.63.2 Constructor & Destructor Documentation

**Line2 ( const Element \* *el* )**

Constructor for an element.

Parameters

in	<i>el</i>	Pointer to element
----	-----------	--------------------

**Line2 ( const Side \* *side* )**

Constructor for a side.

Parameters

in	<i>side</i>	Pointer to side
----	-------------	-----------------

**Line2 ( const Edge \* *edge* )**

Constructor for an edge.

Parameters

in	<i>edge</i>	Pointer to edge
----	-------------	-----------------

### 7.63.3 Member Function Documentation

**real\_t Sh ( size\_t *i*, real\_t *s* ) const**

Calculate shape function of a given node at a given point.

Parameters

in	<i>i</i>	<a href="#">Node</a> number (1 or 2).
in	<i>s</i>	Localization of point in natural coordinates (must be between -1 and 1).

**std::vector<Point<real\_t> > DSh ( ) const**

Return partial derivatives of shape functions of element nodes.

Returns

[LocalVect](#) instance of partial derivatives of shape functions *e.g.* `dsh(i).x`, `dsh(i).y`, are partial derivatives of the *i*-th shape function.

**Point<real\_t> getRefCoord ( const Point< real\_t > & x )**

Return reference coordinates of a point x in element.

Only the x-coordinate of the returned value has a meaning

**real\_t interpolate ( const Point< real\_t > & x, const LocalVect< real\_t, 2 > & v )**

Return interpolated value at a given point.

Parameters

in	<i>x</i>	<a href="#">Point</a> where interpolation is evaluated (in the reference element).
out	<i>v</i>	Computed value.

## 7.64 Line3 Class Reference

To describe a 3-Node quadratic planar line finite element.

Inheritance diagram for Line3:

Collaboration diagram for Line3:

## Public Member Functions

*Return actual coordinates of localized point.*

### 7.64.1 Detailed Description

To describe a 3-Node quadratic planar line finite element.

Defines geometric quantities associated to 3-node quadratic element  $P_2$  in the space. The reference element is the segment  $[-1, 1]$ . The user must take care to the fact that determinant of jacobian and other quantities depend on the point in the reference element where they are calculated. For this, before any utilization of shape functions or jacobian, function [setLocal\(\)](#) must be invoked.

[Element](#) nodes are ordered as the following: the left one, the central one and the right one.

## 7.64.2 Member Function Documentation

**LocalVect<Point<real\_t>,3> DSh ( ) const**

Return partial derivatives of shape functions of element nodes.

Returns

[LocalVect](#) instance of partial derivatives of shape functions *e.g.* `dsh(i).x`, `dsh(i).y`, are partial derivatives of the *i*-th shape function.

Note

The local point at which the derivatives are computed must be chosen before by using the member function `setLocal`

### 7.65.1 Detailed Description

**template<class T\_>class OFELI::LinearSolver< T\_ >**

Class to solve systems of linear equations by iterative methods.

### 7.65.2 Constructor & Destructor Documentation

**LinearSolver ( )**

Default Constructor.

Initializes default parameters and pointers to 0.

**LinearSolver ( int max\_it, real\_t tolerance )**

Constructor with iteration parameters.

Parameters

in	<i>max_it</i>	Maximal number of iterations
in	<i>tolerance</i>	Tolerance for convergence (measured in relative weighted 2-Norm) in input, effective discrepancy in output.

Author

Rachid Touzani

Copyright

GNU Lesser Public License

**LinearSolver ( SpMatrix< T\_ > & A, const Vect< T\_ > & b, Vect< T\_ > & x )**

Constructor using matrix, right-hand side and solution vector.

Parameters

in	<i>A</i>	Reference to instance of class <a href="#">SpMatrix</a>
in	<i>b</i>	<a href="#">Vect</a> instance that contains the right-hand side
in,out	<i>x</i>	<a href="#">Vect</a> instance that contains initial guess on input and solution on output

**LinearSolver ( SkMatrix< T\_ > & A, const Vect< T\_ > & b, Vect< T\_ > & x )**

Constructor using skyline-stored matrix, right-hand side and solution vector.

Parameters

in	<i>A</i>	<a href="#">SkMatrix</a> instance that contains matrix
in	<i>b</i>	<a href="#">Vect</a> instance that contains the right-hand side
in,out	<i>x</i>	<a href="#">Vect</a> instance that contains initial guess on input and solution on output

**LinearSolver ( TrMatrix< T\_ > & A, const Vect< T\_ > & b, Vect< T\_ > & x )**

Constructor using a tridiagonal matrix, right-hand side and solution vector.

Parameters

in	<i>A</i>	<a href="#">TrMatrix</a> instance that contains matrix
in	<i>b</i>	<a href="#">Vect</a> instance that contains the right-hand side
in,out	<i>x</i>	<a href="#">Vect</a> instance that contains initial guess on input and solution on output

**LinearSolver ( BMatrix< T\_ > & A, const Vect< T\_ > & b, Vect< T\_ > & x )**

Constructor using a banded matrix, right-hand side and solution vector.

Parameters

in	$A$	<a href="#">BMatrix</a> instance that contains matrix
in	$b$	<a href="#">Vect</a> instance that contains the right-hand side
in,out	$x$	<a href="#">Vect</a> instance that contains initial guess on input and solution on output

**LinearSolver ( DMatrix< T\_ > & A, const Vect< T\_ > & b, Vect< T\_ > & x )**

Constructor using a dense matrix, right-hand side and solution vector.

Parameters

in	$A$	<a href="#">DMatrix</a> instance that contains matrix
in	$b$	<a href="#">Vect</a> instance that contains the right-hand side
in,out	$x$	<a href="#">Vect</a> instance that contains initial guess on input and solution on output

**LinearSolver ( DSMatrix< T\_ > & A, const Vect< T\_ > & b, Vect< T\_ > & x )**

Constructor using a dense symmetric matrix, right-hand side and solution vector.

Parameters

in	$A$	<a href="#">DSMatrix</a> instance that contains matrix
in	$b$	<a href="#">Vect</a> instance that contains the right-hand side
in,out	$x$	<a href="#">Vect</a> instance that contains initial guess on input and solution on output

**LinearSolver ( SkSMatrix< T\_ > & A, const Vect< T\_ > & b, Vect< T\_ > & x )**

Constructor using skyline-stored symmetric matrix, right-hand side and solution vector.

Parameters

in	$A$	<a href="#">SkMatrix</a> instance that contains matrix
in	$b$	<a href="#">Vect</a> instance that contains the right-hand side
in,out	$x$	<a href="#">Vect</a> instance that contains initial guess on input and solution on output

**LinearSolver ( SkMatrix< T\_ > & A, Vect< T\_ > & b, Vect< T\_ > & x )**

Constructor using matrix, right-hand side.

Parameters

in	$A$	<a href="#">SkMatrix</a> instance that contains matrix
in	$b$	<a href="#">Vect</a> instance that contains the right-hand side
in,out	$x$	<a href="#">Vect</a> instance that contains the initial guess on input and solution on output

### 7.65.3 Member Function Documentation

**void setMaxIter ( int  $m$  )**

Set Maximum number of iterations.

Default value is 1000

**void setMatrix ( OFELI::Matrix< T\_ > \* A )**

Set matrix in the case of a pointer to [Matrix](#).

Parameters

in	A	Pointer to abstract <a href="#">Matrix</a> class
----	---	--

**void setMatrix ( SpMatrix< T\_ > & A )**

Set matrix in the case of a pointer to matrix.

Parameters

in	A	Pointer to abstract <a href="#">Matrix</a> class
----	---	--

**void setMatrix ( SkMatrix< T\_ > & A )**

Set matrix in the case of a skyline matrix.

Parameters

in	A	Matrix as instance of class <a href="#">SkMatrix</a>
----	---	--

**void set ( SpMatrix< T\_ > & A, const Vect< T\_ > & b, Vect< T\_ > & x )**

Set matrix, right-hand side and initial guess.

Parameters

in	A	Reference to matrix as a <a href="#">SpMatrix</a> instance
in	b	Vector containing right-hand side
in,out	x	Vector containing initial guess on input and solution on output

**void setSolver ( Iteration s, Preconditioner p = DIAG\_PREC )**

Set solver and preconditioner.

Parameters

in	s	Solver identification parameter. To be chosen in the enumeration variable Iteration: DIRECT_SOLVER, CG_SOLVER, CGS_SOLVER, BICG_SOLVER, BICG_STAB_SOLVER, GMRES_SOLVER, QMR_SOLVER
in	p	Preconditioner identification parameter. By default, the diagonal preconditioner is used. To be chosen in the enumeration variable Preconditioner: IDENT_PREC, DIAG_PREC, SSOR_PREC, ILU_PREC [Default: ILU_PREC]

Note

The argument p has no effect if the solver is DIRECT\_SOLVER

**int solve ( SpMatrix< T\_ > & A, const Vect< T\_ > & b, Vect< T\_ > & x, Iteration s, Preconditioner p = DIAG\_PREC )**

Solve equations using system data, prescribed solver and preconditioner.

## Parameters

in	$A$	Reference to matrix as a <a href="#">SpMatrix</a> instance
in	$b$	Vector containing right-hand side
in,out	$x$	Vector containing initial guess on input and solution on output
in	$s$	Solver identification parameter To be chosen in the enumeration variable Iteration: DIRECT_SOLVER, CG_SOLVER, CGS_SOLVER, BICG_SOLVER, BICG_ST↔ AB_SOLVER, GMRES_SOLVER, QMR_SOLVER [Default: CGS_SOLVER]
in	$p$	Preconditioner identification parameter. To be chosen in the enumeration variable Preconditioner: IDENT_PREC, DIAG_PREC, SSOR_PREC, ILU_PREC, DILU_PRE↔ C [Default: DIAG_PREC]

## Remarks

The argument  $p$  has no effect if the solver is DIRECT\_SOLVER

## Warning

If the library `eigen` is used, only the preconditioners IDENT\_PREC, DIAG\_PREC and ILU\_PREC are available.

**int solve ( Iteration  $s$ , Preconditioner  $p$  = DIAG\_PREC )**

Solve equations using prescribed solver and preconditioner.

## Parameters

in	$s$	Solver identification parameter To be chosen in the enumeration variable Iteration: DIRECT_SOLVER, CG_SOLVER, CGS_SOLVER, BICG_SOLVER, BICG_ST↔ AB_SOLVER, GMRES_SOLVER, QMR_SOLVER [Default: CGS_SOLVER]
in	$p$	Preconditioner identification parameter. To be chosen in the enumeration variable Preconditioner: IDENT_PREC, DIAG_PREC, SSOR_PREC, DILU_PREC, ILU_PRE↔ C [Default: DIAG_PREC]

## Note

The argument  $p$  has no effect if the solver is DIRECT\_SOLVER

**int solve ( )**

Solve equations all arguments must have been given by other member functions.

Solver and preconditioner parameters must have been set by function `setSolver`. Otherwise, default values are set.

## 7.66 LocalMatrix< T\_, NR\_, NC\_ > Class Template Reference

Handles small size matrices like element matrices, with a priori known size.

### 7.66.1 Detailed Description

**template<class T\_, size\_t NR\_, size\_t NC\_>class OFELI::LocalMatrix< T\_, NR\_, NC\_ >**

Handles small size matrices like element matrices, with a priori known size.

The template class [LocalMatrix](#) treats small size matrices. Typically, this class is recommended to store element and side arrays.

Internally, no dynamic storage is used.

Template Parameters

<i>T_</i>	Data type (double, float, complex<double>, ...)
<i>NR_</i>	number of rows of matrix
<i>NC_</i>	number of columns of matrix

Author

Rachid Touzani

Copyright

GNU Lesser Public License

### 7.66.2 Constructor & Destructor Documentation

**LocalMatrix ( )**

Default constructor.

Constructs a matrix with 0 rows and 0 columns

**LocalMatrix ( Element \*el, const [SpMatrix](#)< T\_ > &a )**

Constructor of a local matrix associated to element from a [SpMatrix](#).

Parameters

in	<i>el</i>	Pointer to <a href="#">Element</a>
in	<i>a</i>	Global matrix as instance of class <a href="#">SpMatrix</a> .

**LocalMatrix ( Element \* *el*, const SkMatrix< T\_ > & *a* )**

Constructor of a local matrix associated to element from a [SkMatrix](#).

Parameters

in	<i>el</i>	Pointer to <a href="#">Element</a>
in	<i>a</i>	Global matrix as instance of class <a href="#">SkMatrix</a> .

**LocalMatrix ( Element \* *el*, const SkSMatrix< T\_ > & *a* )**

Constructor of a local matrix associated to element from a [SkSMatrix](#).

Parameters

in	<i>el</i>	Pointer to <a href="#">Element</a>
in	<i>a</i>	Global matrix as instance of class <a href="#">SkSMatrix</a> .

### 7.66.3 Member Function Documentation

**T\_& operator() ( size\_t *i*, size\_t *j* )**

Operator () (Non constant version)

Returns entry at row *i* and column *j*.

**T\_ operator() ( size\_t *i*, size\_t *j* ) const**

Operator () (Constant version)

Returns entry at row *i* and column *j*.

**void Localize ( Element \* *el*, const SpMatrix< T\_ > & *a* )**

Initialize matrix as element matrix from global [SpMatrix](#).

Parameters

in	<i>el</i>	Pointer to <a href="#">Element</a>
in	<i>a</i>	Global matrix as instance of class <a href="#">SpMatrix</a> . This function is called by its corresponding constructor.

**void Localize ( Element \* *el*, const SkMatrix< T\_ > & *a* )**

Initialize matrix as element matrix from global [SkMatrix](#).

Parameters

in	<i>el</i>	Pointer to <a href="#">Element</a>
in	<i>a</i>	Global matrix as instance of class <a href="#">SkMatrix</a> . This function is called by its corresponding constructor.

**void Localize ( Element \* *el*, const SkSMatrix< T\_ > & *a* )**

Initialize matrix as element matrix from global [SkSMatrix](#).

Parameters

in	<i>el</i>	Pointer to <a href="#">Element</a>
in	<i>a</i>	Global matrix as instance of class <a href="#">SkSMatrix</a> . This function is called by its corresponding constructor.

**LocalMatrix<T\_,NR\_,NC\_>& operator= ( const LocalMatrix< T\_, NR\_, NC\_ > & m )**

Operator =

Copy instance m into current instance.

**LocalMatrix<T\_,NR\_,NC\_>& operator= ( const T\_ & x )**

Operator =

Assign matrix to identity times x

**LocalMatrix<T\_,NR\_,NC\_>& operator+= ( const LocalMatrix< T\_, NR\_, NC\_ > & m )**

Operator +=

Add m to current matrix.

**LocalMatrix<T\_,NR\_,NC\_>& operator-= ( const LocalMatrix< T\_, NR\_, NC\_ > & m )**

Operator -=

Subtract m from current matrix.

**LocalVect<T\_,NR\_> operator\* ( LocalVect< T\_, NC\_ > & x )**

Operator \*

Return a [Vect](#) instance as product of current matrix by vector x.

**LocalMatrix<T\_,NR\_,NC\_>& operator+= ( const T\_ & x )**

Operator +=

Add constant x to current matrix entries.

**LocalMatrix<T\_,NR\_,NC\_>& operator-= ( const T\_ & x )**

Operator -=

Subtract x from current matrix entries.

**LocalMatrix<T\_,NR\_,NC\_>& operator\*= ( const T\_ & x )**

Operator \*=

Multiply matrix entries by constant x.

**LocalMatrix<T\_,NR\_,NC\_>& operator/= ( const T\_ & x )**

Operator /=

Divide by x current matrix entries.

**void MultAdd ( const LocalVect< T\_, NC\_ > & x, LocalVect< T\_, NR\_ > & y )**

Multiply matrix by vector and add result to vector.

Parameters

in	$x$	Vector to multiply matrix by.
out	$y$	Resulting vector ( $y += a * x$ )

**void MultAddScal ( const T\_ & a, const LocalVect< T\_, NC\_ > & x, LocalVect< T\_, NR\_ > & y )**

Multiply matrix by scaled vector and add result to vector.

Parameters

in	$a$	Constant to premultiply by vector x.
in	$x$	(Scaled) vector to multiply matrix by.
out	$y$	Resulting vector ( $y += a * x$ )

**void Mult ( const LocalVect< T\_, NC\_ > & x, LocalVect< T\_, NR\_ > & y )**

Multiply matrix by vector.

Parameters

in	$x$	Vector to multiply matrix by.
out	$y$	Resulting vector.

**void Symmetrize ( )**

Symmetrize matrix.

Fill upper triangle to form a symmetric matrix.

**int Factor ( )**

Factorize matrix.

Performs a LU factorization.

Returns

- 0: Factorization has ended normally,
- n: n-th pivot was zero.

**int solve ( LocalVect< T\_, NR\_ > & b )**

Forward and backsubstitute to solve a linear system.

Parameters

in	$b$	Right-hand side in input and solution vector in output.
----	-----	---

Returns

- 0: Solution was performed normally.
- n: n-th pivot is zero.

Note

Matrix must have been factorized at first.

**int FactorAndSolve ( LocalVect< T\_, NR\_ > & *b* )**

Factorize matrix and solve linear system.

Parameters

in,out	$b$	Right-hand side in input and solution vector in output.
--------	-----	---

Returns

0 if solution was performed normally.  $n$  if  $n$ -th pivot is zero. This function simply calls **Factor()** then **Solve(b)**.

**void Invert ( LocalMatrix< T\_, NR\_, NC\_ > & A )**

Calculate inverse of matrix.

Parameters

out	$A$	Inverse of matrix
-----	-----	-------------------

**T\_ getInnerProduct ( const LocalVect< T\_, NC\_ > & x, const LocalVect< T\_, NR\_ > & y )**

Calculate inner product with respect to matrix.

Returns the product  $x^T A y$

Parameters

in	$x$	Left vector
in	$y$	Right vector

Returns

Resulting product

## 7.67 LocalVect< T\_, N\_ > Class Template Reference

### 7.67.1 Detailed Description

**template<class T\_, size\_t N\_>class OFELI::LocalVect< T\_, N\_ >**

Handles small size vectors like element vectors.

The template class [LocalVect](#) treats small size vectors. Typically, this class is recommended to store element and side arrays. Operators =, [] and () are overloaded so that one can write for instance:

```
LocalVect<double,10> u, v;
v = -1.0;
u = v;
u(3) = -2.0;
```

to set vector **v** entries to **-1**, copy vector **v** into vector **u** and assign third entry of **v** to **-2**. Notice that entries of **v** are here **v(1)**, **v(2)**, ..., **v(10)**, *i.e.* vector entries start at index 1. Internally, no dynamic storage is used.

Template Parameters

<i>T_</i>	Data type (double, float, complex<double>, ...)
<i>N_</i>	Vector size

Author

Rachid Touzani

Copyright

GNU Lesser Public License

### 7.67.2 Constructor & Destructor Documentation

**LocalVect ( const Element \* *el*, const Vect< T\_ > & *v*, int *opt* = 0 )**

Constructor of an element vector from a global [Vect](#) instance.

The constructed vector has local numbering of nodes

Parameters

in	<i>el</i>	Pointer to <a href="#">Element</a> to localize
in	<i>v</i>	Global vector to localize
in	<i>opt</i>	Option for DOF treatment <ul style="list-style-type: none"> <li>• = 0, Normal case [Default]</li> <li>• Any other value : only one DOF is handled (Local vector has as dimension number of degrees of freedom)</li> </ul>

**LocalVect ( const Element & *el*, const Vect< T\_ > & *v*, int *opt* = 0 )**

Constructor of an element vector from a global [Vect](#) instance.

The constructed vector has local numbering of nodes

Parameters

in	<i>el</i>	Reference to <a href="#">Element</a> instance to localize
in	<i>v</i>	Global vector to localize
in	<i>opt</i>	Option for DOF treatment <ul style="list-style-type: none"> <li>• = 0, Normal case [Default]</li> <li>• Any other value : only one DOF is handled (Local vector has as dimension number of degrees of freedom)</li> </ul>

**LocalVect ( const Side \* *sd*, const Vect< T\_ > & *v*, int *opt* = 0 )**

Constructor of a side vector from a global [Vect](#) instance.

The constructed vector has local numbering of nodes

Parameters

in	<i>sd</i>	Pointer to <a href="#">Side</a> to localize
in	<i>v</i>	Global vector to localize
in	<i>opt</i>	Option for DOF treatment <ul style="list-style-type: none"> <li>• = 0, Normal case [Default]</li> <li>• Any other value : only one DOF is handled (Local vector has as dimension number of degrees of freedom)</li> </ul>

### 7.67.3 Member Function Documentation

**void getLocal ( const Element & *el*, const Vect< T\_ > & *v*, int *type* )**

Localize an element vector from a global [Vect](#) instance.

The constructed vector has local numbering of nodes This function is called by the constructor↵  
: LocalVect(const Element \**el*, const Vect<T\_> &*v*)

Parameters

in	<i>el</i>	Pointer to <a href="#">Element</a> to localize
in	<i>v</i>	Global vector to localize
in	<i>type</i>	Type of element. This is to be chosen among enumerated values: LINE2, TRIANG3, QUAD4, TETRA4, HEXA8, PENTA6

**void Localize ( const Element \* *el*, const Vect< T\_ > & *v*, size\_t *k* = 0 )**

Localize an element vector from a global [Vect](#) instance.

The constructed vector has local numbering of nodes This function is called by the constructor↵  
: LocalVect(const Element \**el*, const Vect<T\_> &*v*)

Parameters

in	<i>el</i>	Pointer to <a href="#">Side</a> to localize
in	<i>v</i>	Global vector to localize
in	<i>k</i>	Degree of freedom to localize [Default: All degrees of freedom are stored]

**void Localize ( const Side \* *sd*, const Vect< T\_ > & *v*, size\_t *k* = 0 )**

Localize a side vector from a global Vect instance.

The constructed vector has local numbering of nodes This function is called by the constructor  
**: LocalVect(const Side \**sd*, const Vect<T\_> &*v*)**

Parameters

in	<i>sd</i>	Pointer to Side to localize
in	<i>v</i>	Global vector to localize
in	<i>k</i>	Degree of freedom to localize [Default: All degrees of freedom are stored]

**T\_& operator[] ( size\_t *i* )**

Operator [] (Non constant version).

*v*[*i*] starts at *v*[0] to *v*[size()-1]

**T\_ operator[] ( size\_t *i* ) const**

Operator [] (Constant version).

*v*[*i*] starts at *v*[0] to *v*[size()-1]

**T\_& operator() ( size\_t *i* )**

Operator () (Non constant version).

*v*(*i*) starts at *v*(1) to *v*(size()). *v*(*i*) is the same element as *v*[*i*-1]

**T\_ operator() ( size\_t *i* ) const**

Operator () (Constant version).

*v*(*i*) starts at *v*(1) to *v*(size()) *v*(*i*) is the same element as *v*[*i*-1]

**LocalVect<T\_,N\_>& operator= ( const LocalVect< T\_, N\_ > & *v* )**

Operator =

Copy a LocalVect instance to the current one

**LocalVect<T\_,N\_>& operator= ( const T\_ & *x* )**

Operator =

Assign value *x* to all vector entries

**LocalVect<T\_,N\_>& operator+= ( const LocalVect< T\_, N\_ > & *v* )**

Operator +=

Add vector *v* to this instance

**LocalVect<T\_,N\_>& operator+= ( const T\_ & *a* )**

Operator +=

Add constant *a* to vector entries

**LocalVect<T\_,N\_>& operator-= ( const LocalVect< T\_, N\_ > & v )**

Operator -=

Subtract vector v from this instance

**LocalVect<T\_,N\_>& operator-= ( const T\_ & a )**

Operator -=

Subtract constant a from vector entries

**LocalVect<T\_,N\_>& operator\*= ( const T\_ & a )**

Operator \*=

Multiply vector by constant a

**LocalVect<T\_,N\_>& operator/= ( const T\_ & a )**

Operator /=

Divide vector by constant a

**T\_ operator, ( const LocalVect< T\_, N\_ > & v ) const**

Return Dot (scalar) product of two vectors.

A typical use of this operator is double a = (v,w) where v and w are 2 instances of LocalVect<double,n>

Parameters

in	v	LocalVect instance by which the current instance is multiplied
----	---	--

### 7.68.1 Detailed Description

To solve a linear programming problem.

The Linear Program reads:

```
Minimise: d(1)*x(1) + ... + d(n)*x(n) + e
Subject to the constraints:
    A(i,1)*x(1) + ... + A(i,n)*x(n) <= a(i)  i=1,...,n_le
    B(i,1)*x(1) + ... + B(i,n)*x(n) >= b(i)  i=1,...,n_ge
    C(i,1)*x(1) + ... + C(i,n)*x(n) =  c(i)  i=1,...,n_eq
    x(i) >= 0, 1<=i<=n
```

Solution is held by the Simplex method Reference: "Numerical Recipes By W.H. Press, B. P. Flannery, S.A. Teukolsky and W.T. Vetterling, Cambridge University Press, 1986"

C-implementation copied from J-P Moreau, Paris

### 7.68.2 Member Enumeration Documentation

#### enum Setting

Selects setting option: Objective or Constraints

Enumerator

**OBJECTIVE** Objective function coefficients

**LE\_CONSTRAINT** 'Less or Equal' constraint coefficients

**GE\_CONSTRAINT** 'Greater or Equal' constraint coefficients

**EQ\_CONSTRAINT** 'Equality' constraint coefficients

### 7.68.3 Constructor & Destructor Documentation

`LPSolver ( int nv, int nb_le, int nb_ge, int nb_eq )`

Constructor using Linear Program data.

Parameters

<code>in</code>	<code>nv</code>	Number of optimization variables
<code>in</code>	<code>nb_le</code>	Number of '<=' inequality constraints
<code>in</code>	<code>nb_ge</code>	Number of '>=' inequality constraints
<code>in</code>	<code>nb_eq</code>	Number of '=' equality constraints

#### 7.68.4 Member Function Documentation

**void setSize ( int *nv*, int *nb\_le*, int *nb\_ge*, int *nb\_eq* )**

Set optimization parameters.

Parameters

<code>in</code>	<code>nv</code>	Number of optimization variables
<code>in</code>	<code>nb_le</code>	Number of '<=' inequality constraints
<code>in</code>	<code>nb_ge</code>	Number of '>=' inequality constraints
<code>in</code>	<code>nb_eq</code>	Number of '=' equality constraints

**void set ( Vect< real.t > & *x* )**

vector of optimization variables

Parameters

<code>in</code>	<code>x</code>	Vector of optimization variables. Its size must be at least equal to number of optimization variables
-----------------	----------------	---

**void set ( Setting *opt*, const Vect< real.t > & *a*, real.t *b* = 0.0 )**

Set optimization data.

This function enables providing all optimization data. It has to be used for the objective function and once for each constraint.

Parameters

<code>in</code>	<code>opt</code>	Option for data, to choose among enumerated values: <ul style="list-style-type: none"> <li>• OBJECTIVE To set objective function to minimize</li> <li>• LE_CONSTRAINT To set a '&lt;=' inequality constraint</li> <li>• GE_CONSTRAINT To set a '&gt;=' inequality constraint</li> <li>• EQ_CONSTRAINT To set an equality constraint</li> </ul>
-----------------	------------------	--

in	$a$	Vector coefficients if the chosen function. If <code>opt==OBJECTIVE</code> , vector components are the coefficients multiplying the variables in the objective function. if <code>xx.CONSTRAINT</code> , vector components are the coefficients multiplying the variables in the corresponding constraint.
in	$b$	Constant value in the objective function or in a constraint. Its default value is 0.0

**int run ( )**

Run the linear program solver.

This function runs the linear programming solver using the Simplex algorithm

Returns

0 if process is complete, >0 otherwise

**real\_t getObjective ( ) const**

Return objective.

Once execution is complete, this function returns optimal value of objective

## 7.69 Material Class Reference

To treat material data. This class enables reading material data in material data files. It also returns these informations by means of its members.

- [real\\_t ElectricResistivity \(const Point< real\\_t > &x, real\\_t t\)](#)

*Return electric resistivity at point  $x$  and time  $t$*
- [real\\_t MagneticPermeability \(\)](#)

*Return constant magnetic permeability.*
- [real\\_t MagneticPermeability \(const Point< real\\_t > &x, real\\_t t\)](#)

*Return magnetic permeability at point  $x$  and time  $t$*
- [real\\_t Viscosity \(\)](#)

*Return constant viscosity.*

- `real_t Viscosity` (const `Point< real_t >` &x, `real_t` t)

*Return viscosity at point x and time t*

- `real_t YoungModulus` ()

*Return constant Young modulus.*

- `real_t YoungModulus` (const `Point< real_t >` &x, `real_t` t)

*Return Young modulus at point x and time t*

- `real_t PoissonRatio` ()

*Return constant Poisson ratio.*

- `real_t PoissonRatio` (const `Point< real_t >` &x, `real_t` t)

*Return Poisson ratio at point x and time t*

- `real_t Property` (int i)

*Return constant i-th property.*

- `real_t Property` (int i, const `Point< real_t >` &x, `real_t` t)

*Return i-th property at point x and time t*

- `Material & operator=` (const `Material` &m)

*Operator =.*

### 7.69.1 Detailed Description

To treat material data. This class enables reading material data in material data files. It also returns these informations by means of its members.

### 7.69.2 Constructor & Destructor Documentation

**Material ( )**

Default constructor.

It initializes the class and searches for the path where are material data files.

### 7.69.3 Member Function Documentation

**int set ( int m, const string & name )**

Associate to material code number n the material named name

Returns

Number of materials

**string getName ( int m ) const**

Return material name for material with code m

If such a material is not found, return a blank string.

**int check ( int c )**

Check if material code c is present.

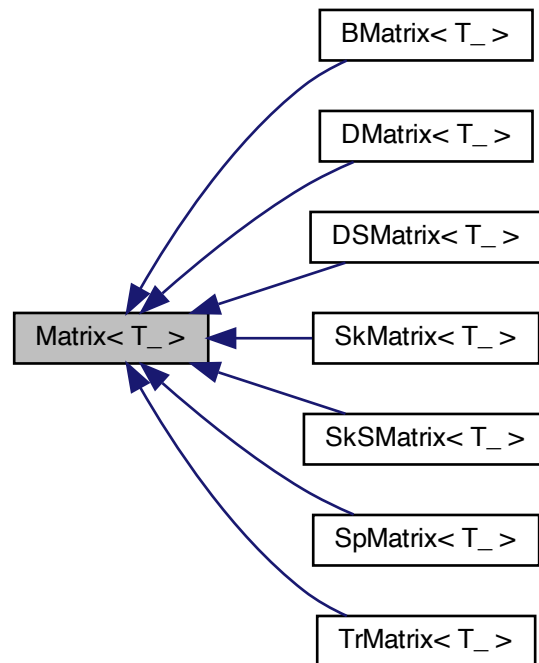

Returns

0 if succeeded, 1 if not.

## 7.70 Matrix< T\_ > Class Template Reference

Virtual class to handle matrices for all storage formats.

### 7.70.1 Detailed Description

**template<class T\_>class OFELI::Matrix< T\_ >**

Virtual class to handle matrices for all storage formats.

This class enables storing and manipulating dense matrices. The template parameter is the type of matrix entries. Any matrix entry can be accessed by the () operator: For instance, if A is an instance of this class, A(*i*, *j*) stands for the entry at the *i*-th row and *j*-th column, *i* and *j* starting from 1. Entries of A can be assigned a value by the same operator.

## Template Parameters

<T_>	Data type (real_t, float, complex<real_t>, ...)
------	---

## Author

Rachid Touzani

## Copyright

GNU Lesser Public License

**7.70.2 Constructor & Destructor Documentation****Matrix ( )**

Default constructor.

Initializes a zero-size matrix.

**7.70.3 Member Function Documentation****virtual void reset ( ) [virtual]**

Set matrix to 0 and reset factorization parameter.

## Warning

This function must be used if after a factorization, the matrix has been modified

Reimplemented in [DMatrix< T\\_ >](#), and [DMatrix< real\\_t >](#).**T\_ getDiag ( size\_t k ) const**

Return k-th diagonal entry of matrix.

First entry is given by **getDiag(1)**.**virtual void Axy ( T\_ a, const Matrix< T\_ > \* x ) [pure virtual]**

Add to matrix the product of a matrix by a scalar.

## Parameters

in	<i>a</i>	Scalar to premultiply
in	<i>x</i>	Matrix by which a is multiplied. The result is added to current instance

Implemented in [SpMatrix< T\\_ >](#), [SpMatrix< real\\_t >](#), [DSMatrix< T\\_ >](#), [DSMatrix< real\\_t >](#), [DMatrix< T\\_ >](#), [DMatrix< real\\_t >](#), [SkSMatrix< T\\_ >](#), [SkMatrix< T\\_ >](#), [TrMatrix< T\\_ >](#), [BMatrix< T\\_ >](#), and [BMatrix< real\\_t >](#).

**void setDiagonal ( Mesh & mesh )**

Initialize matrix storage in the case where only diagonal terms are stored.

This member function is to be used for explicit time integration schemes

**void Assembly ( const Element & el, T\_ \* a )**

Assembly of element matrix into global matrix.

Case where element matrix is given by a C-array.

Parameters

in	<i>el</i>	Pointer to element instance
in	<i>a</i>	<a href="#">Element</a> matrix as a C-array

**void Assembly ( const Side & *sd*, T\_ \* *a* )**

Assembly of side matrix into global matrix.

Case where side matrix is given by a C-array.

Parameters

in	<i>sd</i>	Pointer to side instance
in	<i>a</i>	<a href="#">Side</a> matrix as a C-array instance

**void Prescribe ( Vect< T\_ > & *b*, const Vect< T\_ > & *u*, int *flag* = 0 )**

Impose by a penalty method an essential boundary condition, using the [Mesh](#) instance provided by the constructor.

This member function modifies diagonal terms in matrix and terms in vector that correspond to degrees of freedom with nonzero code in order to impose a boundary condition. The penalty parameter is defined by default equal to 1.e20. It can be modified by member function **setPenal(..)**.

Parameters

in,out	<i>b</i>	<a href="#">Vect</a> instance that contains right-hand side.
in	<i>u</i>	<a href="#">Vect</a> instance that contains imposed valued at DOFs where they are to be imposed.
in	<i>flag</i>	Parameter to determine whether only the right-hand side is to be modified ( <i>dof</i> >0) or both matrix and right-hand side ( <i>dof</i> =0, default value).

**void Prescribe ( int *dof*, int *code*, Vect< T\_ > & *b*, const Vect< T\_ > & *u*, int *flag* = 0 )**

Impose by a penalty method an essential boundary condition to a given degree of freedom for a given code.

This member function modifies diagonal terms in matrix and terms in vector that correspond to degrees of freedom with nonzero code in order to impose a boundary condition. The penalty parameter is defined by default equal to 1.e20. It can be modified by member function **setPenal(..)**.

Parameters

in	<i>dof</i>	Degree of freedom for which a boundary condition is to be enforced
in	<i>code</i>	Code for which a boundary condition is to be enforced
in,out	<i>b</i>	<a href="#">Vect</a> instance that contains right-hand side.
in	<i>u</i>	<a href="#">Vect</a> instance that contains imposed valued at DOFs where they are to be imposed.

in	flag	Parameter to determine whether only the right-hand side is to be modified (dof>0) or both matrix and right-hand side (dof=0, default value).
----	------	--

**void Prescribe ( Vect< T\_ > & b, int flag = 0 )**

Impose by a penalty method a homegeneous (=0) essential boundary condition.

This member function modifies diagonal terms in matrix and terms in vector that correspond to degrees of freedom with nonzero code in order to impose a boundary condition. The penalty parameter is defined by default equal to 1.e20. It can be modified by member function **setPenal(..)**.

Parameters

in,out	b	<a href="#">Vect</a> instance that contains right-hand side.
in	flag	Parameter to determine whether only the right-hand side is to be modified (dof>0) or both matrix and right-hand side (dof=0, default value).

**void Prescribe ( size\_t dof, Vect< T\_ > & b, const Vect< T\_ > & u, int flag = 0 )**

Impose by a penalty method an essential boundary condition when only one DOF is treated.

This member function modifies diagonal terms in matrix and terms in vector that correspond to degrees of freedom with nonzero code in order to impose a boundary condition. This gunction is to be used if only one DOF per node is treated in the linear system. The penalty parameter is by default equal to 1.e20. It can be modified by member function **setPenal**.

Parameters

in	dof	Label of the concerned degree of freedom (DOF).
in,out	b	<a href="#">Vect</a> instance that contains right-hand side.
in	u	<a href="#">Vect</a> instance that conatins imposed valued at DOFs where they are to be imposed.
in	flag	Parameter to determine whether only the right-hand side is to be modified (dof>0) or both matrix and right-hand side (dof=0, default value).

**void PrescribeSide ( )**

Impose by a penalty method an essential boundary condition when DOFs are supported by sides.

This member function modifies diagonal terms in matrix and terms in vector that correspond to degrees of freedom with nonzero code in order to impose a boundary condition. The penalty parameter is defined by default equal to 1.e20. It can be modified by member function **setPenal(..)**.

**virtual int solve ( Vect< T\_ > & b, bool fact = true )** [pure virtual]

Solve the linear system.

If the inherited class is [SpMatrix](#), the function uses an iterative method once this one has been chosen. Otherwise, the method solves the linear system by factorization.

Implemented in [DMatrix< T\\_ >](#), [DMatrix< real.t >](#), [SkSMatrix< T\\_ >](#), [SkMatrix< T\\_ >](#), [DMatrix< T\\_ >](#), [DSMatrix< real.t >](#), [BMatrix< T\\_ >](#), [BMatrix< real.t >](#), and [TrMatrix< T\\_ >](#).

**virtual int solve ( const Vect< T\_ > & b, Vect< T\_ > & x, bool fact = true )** [pure virtual]

Solve the linear system.

If the inherited class is [SpMatrix](#), the function uses an iterative method once this one has been chosen. Otherwise, the method solves the linear system by factorization.

Parameters

in	<i>b</i>	<a href="#">Vect</a> instance that contains right-hand side
out	<i>x</i>	<a href="#">Vect</a> instance that contains solution
in	<i>fact</i>	Set to true if factorization is to be performed, false if not. [Default: true]

Returns

- 0 if solution was normally performed
  - *n* if the *n*-th pivot is null
- Solution is performed only if factorization has previously been invoked.

Implemented in [SpMatrix< T\\_ >](#), [SpMatrix< real.t >](#), [DMatrix< T\\_ >](#), [DMatrix< real.t >](#), [SkSMMatrix< T\\_ >](#), [SkMatrix< T\\_ >](#), [DSMatrix< T\\_ >](#), [DSMatrix< real.t >](#), [BMatrix< T\\_ >](#), [BMatrix< real.t >](#), and [TrMatrix< T\\_ >](#).

**int FactorAndSolve ( Vect< T\_ > & b )**

Factorize matrix and solve the linear system.

This is available only if the storage class enables it.

Parameters

in,out	<i>b</i>	<a href="#">Vect</a> instance that contains right-hand side on input and solution on output
--------	----------	---

**int FactorAndSolve ( const Vect< T\_ > & b, Vect< T\_ > & x )**

Factorize matrix and solve the linear system.

This is available only if the storage class enables it.

Parameters

in	<i>b</i>	<a href="#">Vect</a> instance that contains right-hand side
out	<i>x</i>	<a href="#">Vect</a> instance that contains solution

Returns

- 0 if solution was normally performed
- *n* if the *n*-th pivot is null

**int isFactorized ( ) const**

Say if matrix is factorized or not.

If the matrix was not factorized, the class does not allow solving by a direct solver.

**virtual void set ( size\_t i, size\_t j, const T\_ & val )** [pure virtual]

Assign a value to an entry of the matrix.

Parameters

<code>in</code>	<code>i</code>	Row index
<code>in</code>	<code>j</code>	Column index
<code>in</code>	<code>val</code>	Value to assign

Implemented in [SpMatrix< T\\_ >](#), [SpMatrix< real\\_t >](#), [SkSMatrix< T\\_ >](#), [DMatrix< T\\_ >](#), [DMatrix< real\\_t >](#), [SkMatrix< T\\_ >](#), [TrMatrix< T\\_ >](#), [BMatrix< T\\_ >](#), [BMatrix< real\\_t >](#), [DSMatrix< T\\_ >](#), and [DSMatrix< real\\_t >](#).

**virtual T\_ & operator() ( size\_t i, size\_t j )** [pure virtual]

Operator () (Non constant version).

Returns the (i, j) entry of the matrix.

Parameters

<code>in</code>	<code>i</code>	Row index
<code>in</code>	<code>j</code>	Column index

Implemented in [SpMatrix< T\\_ >](#), [SpMatrix< real\\_t >](#), [DMatrix< T\\_ >](#), [DMatrix< real\\_t >](#), [SkSMatrix< T\\_ >](#), [SkMatrix< T\\_ >](#), [DSMatrix< T\\_ >](#), [DSMatrix< real\\_t >](#), [TrMatrix< T\\_ >](#), [BMatrix< T\\_ >](#), and [BMatrix< real\\_t >](#).

**virtual T\_ operator() ( size\_t i, size\_t j ) const** [pure virtual]

Operator () (Non constant version).

Returns the (i, j) entry of the matrix.

Parameters

<code>in</code>	<code>i</code>	Row index
<code>in</code>	<code>j</code>	Column index

Implemented in [SpMatrix< T\\_ >](#), [SpMatrix< real\\_t >](#), [DMatrix< T\\_ >](#), [DMatrix< real\\_t >](#), [SkSMatrix< T\\_ >](#), [SkMatrix< T\\_ >](#), [DSMatrix< T\\_ >](#), [DSMatrix< real\\_t >](#), [TrMatrix< T\\_ >](#), [BMatrix< T\\_ >](#), and [BMatrix< real\\_t >](#).

**T\_ operator() ( size\_t i ) const**

Operator () with one argument (Constant version).

Returns i-th position in the array storing matrix entries. The first entry is at location 1. Entries are stored row by row.

Parameters

<code>in</code>	<code>i</code>	entry index
-----------------	----------------	-------------

**T\_ & operator() ( size\_t i )**

Operator () with one argument (Non Constant version).

Returns i-th position in the array storing matrix entries. The first entry is at location 1. Entries are stored row by row.

Parameters

<code>in</code>	<code>i</code>	entry index
-----------------	----------------	-------------

**T\_& operator[] ( size\_t k )**

Operator [] (Non constant version).

Returns k-th stored element in matrix Index k starts at 0.

**T\_ operator[] ( size\_t k ) const**

Operator [] (Constant version).

Returns k-th stored element in matrix Index k starts at 0.

**Matrix& operator= ( Matrix< T\_ > & m )**

Operator =.

Copy matrix m to current matrix instance.

**Matrix& operator+= ( const Matrix< T\_ > & m )**

Operator +=.

Add matrix m to current matrix instance.

**Matrix& operator-= ( const Matrix< T\_ > & m )**

Operator -=.

Subtract matrix m from current matrix instance.

**Matrix& operator= ( const T\_ & x )**

Operator =.

Assign constant value x to all matrix entries.

**Matrix& operator\*= ( const T\_ & x )**

Operator \*.

Premultiply matrix entries by constant value x

**Matrix& operator+= ( const T\_ & x )**

Operator +=.

Add constant value x to all matrix entries.

**Matrix& operator-= ( const T\_ & x )**

Operator -=.

Subtract constant value x from all matrix entries.

## 7.71 Mesh Class Reference

To store and manipulate finite element meshes.

## Public Member Functions

- Return number of internal sides.*

  - size\_t [getNbMat](#) () const
- Return number of materials.*

  - void [AddMidNodes](#) (int g=0)

- *Add mid-side nodes.*
- `Point< real_t > getMaxCoord () const`  
*Return maximum coordinates of nodes.*
- `Point< real_t > getMinCoord () const`  
*Return minimum coordinates of nodes.*
- `void set (Node *nd)`  
*Replace node in the mesh.*
- `void set (Element *el)`  
*Replace element in the mesh.*
- `void set (Side *sd)`  
*Choose side in the mesh.*
- `bool NodesAreDOF () const`  
*Return information about DOF type.*
- `bool SidesAreDOF () const`  
*Return information about DOF type.*
- `bool EdgesAreDOF () const`  
*Return information about DOF type.*
- `bool ElementsAreDOF () const`  
*Return information about DOF type.*
- `int getDOFSupport () const`  
*Return information on dof support Return an integer according to enumerated values: NODE\_DOF, ELEMENT\_DOF, SIDE\_DOF.*
- `void Deform (const Vect< real_t > &u, real_t rate=0.2)`  
*Deform mesh according to a displacement vector.*
- `void put (const string &mesh_file) const`  
*Write mesh data on file.*
- `void save (const string &mesh_file) const`  
*Write mesh data on file in various formats.*
- `bool withImposedDOF () const`  
*Return true if imposed DOF count in equations, false if not.*
- `bool isStructured () const`  
*Return true is mesh is structured, false if not.*
- `size_t getNodeNewLabel (size_t n) const`  
*Return new label of node of a renumbered node.*
- `void getList (vector< Node * > &nl) const`  
*Fill vector nl with list of pointers to nodes.*
- `void getList (vector< Element * > &el) const`  
*Fill vector el with list of pointers to elements.*
- `void getList (vector< Side * > &sl) const`  
*Fill vector sl with list of pointers to sides.*
- `Node * getPtrNode (size_t i) const`  
*Return pointer to node with label i.*
- `Node & getNode (size_t i) const`  
*Return refernce to node with label i*
- `Element * getPtrElement (size_t i) const`  
*Return pointer to element with label i*
- `Element & getElement (size_t i) const`

- Return reference to element with label  $i$*

  - `Side * getPtrSide (size_t i) const`

*Return pointer to side with label  $i$*

  - `Side & getSide (size_t i) const`

*Return reference to side with label  $i$*

  - `Edge * getPtrEdge (size_t i) const`

*Return pointer to edge with label  $i$*

  - `Edge & getEdge (size_t i) const`

*Return reference to edge with label  $i$*

  - `size_t getNodeLabel (size_t i) const`

*Return label of  $i$ -th node.*

  - `size_t getElementLabel (size_t i) const`

*Return label of  $i$ -th element.*

  - `size_t getSideLabel (size_t i) const`

*Return label of  $i$ -th side.*

  - `size_t getEdgeLabel (size_t i) const`

*Return label of  $i$ -th edge.*

  - `void topNode () const`

*Reset list of nodes at its top position (Non constant version)*

  - `void topBoundaryNode () const`

*Reset list of boundary nodes at its top position (Non constant version)*

  - `void topMarkedNode () const`

*Reset list of marked nodes at its top position (Non constant version)*

  - `void topElement () const`

*Reset list of elements at its top position (Non constant version)*

  - `void topSide () const`

*Reset list of sides at its top position (Non constant version)*

  - `void topBoundarySide () const`

*Reset list of boundary sides at its top position (Non constant version)*

  - `void topInternalSide () const`

*Reset list of intrrenal sides at its top position (Non constant version)*

  - `void topEdge () const`

*Reset list of edges at its top position (Non constant version)*

  - `void topBoundaryEdge () const`

*Reset list of boundary edges at its top position (Non constant version)*

  - `Node * getNode () const`

*Return pointer to current node and move to next one (Non constant version)*

  - `Node * getBoundaryNode () const`

*Return pointer to current boundary node and move to next one (Non constant version)*

  - `Node * getMarkedNode () const`

*Return pointer to current marked node and move to next one (Non constant version)*

  - `Element * getElement () const`

*Return pointer to current element and move to next one (Non constant version)*

  - `Element * getActiveElement () const`

*Return pointer to current element and move to next one (Non constant version)*

  - `Side * getSide () const`

- Return pointer to current side and move to next one (Non constant version)*

  - `Side * getBoundarySide () const`

*Return pointer to current boundary side and move to next one (Non constant version)*

- `Side * getInternalSide () const`

*Return pointer to current internal side and move to next one (Non constant version)*

- `Edge * getEdge () const`

*Return pointer to current edge and move to next one (Non constant version)*

- `Edge * getBoundaryEdge () const`

*Return pointer to current boundary edge and move to next one (Non constant version)*

- `int getShape () const`

*Determine shape of elements Return Shape index (see enum ElementShape) if all elements have the same shape, 0 if not.*

- `Element * operator() (size_t i) const`

*Operator () : Return pointer to i-th element.*

- `Node * operator[] (size_t i) const`

*Operator [] : Return pointer to i-th node.*

- `size_t operator() (size_t i, size_t n) const`

*Operator () : Return pointer to i-th node of n-th element.*

- `Mesh & operator= (Mesh &ms)`

*Operator = : Assign a Mesh instance.*

## Friends

- `void Refine (Mesh &in_mesh, Mesh &out_mesh)`
- Refine mesh. Subdivide each triangle into 4 subtriangles. This member function is valid for 2-D triangular meshes only.*

### 7.71.1 Detailed Description

To store and manipulate finite element meshes.

Class `Mesh` enables defining as an object a finite element mesh. A finite element mesh is characterized by its nodes, elements and sides. Each of these types of data constitutes a class in the `OFELI` library.

The standard procedure to introduce the finite element mesh is to provide an input file containing its data. For this, we have defined our own mesh data file (following the XML syntax). Of course, a developer can write his own function to read his finite element mesh file using the methods in `Mesh`.

### 7.71.2 Constructor & Destructor Documentation

`Mesh ( const string & file, bool bc = false, int opt = NODE_DOF, int nb_dof = 1 )`

Constructor using a mesh file.

## Parameters

in	<i>file</i>	File containing mesh data. The extension of the file yields the file format: The extension .m implies <a href="#">OFELI</a> file format and .msh implies GMSH msh file.
in	<i>bc</i>	Flag to remove (true) or not (false) imposed Degrees of Freedom [default: false]
in	<i>opt</i>	Type of DOF support: To choose among enumerated values NO↔DE_DOF, SIDE_DOF or ELEMENT_DOF. Say if degrees of freedom (unknowns) are supported by nodes, sides or elements.
in	<i>nb_dof</i>	Number of degrees of freedom per node [Default: 1].

**Mesh ( real\_t xmin, real\_t xmax, size\_t nb\_el, size\_t p = 1, size\_t nb\_dof = 1 )**

Constructor for a 1-D mesh. The domain is the interval [xmin,xmax].

## Parameters

in	<i>xmin</i>	Value of xmin
in	<i>xmax</i>	Value of xmax
in	<i>nb_el</i>	Number of elements to generate
in	<i>p</i>	Degree of finite element polynomial (Default = 1)
in	<i>nb_dof</i>	Number of degrees of freedom for each node (Default = 1)

**Mesh ( const Grid & g, int opt = QUADRILATERAL )**

Constructor for a uniform finite difference grid given by and instance of class [Grid](#).

## Parameters

in	<i>g</i>	<a href="#">Grid</a> instance
in	<i>opt</i>	Optional value to say which type of elements to generate <ul style="list-style-type: none"> <li>• TRIANGLE: Mesh elements are triangles</li> <li>• QUADRILATERAL: Mesh elements are quadrilaterals [default]</li> </ul>

**Mesh ( const Grid & g, int shape, int opt )**

Constructor of dual mesh for a uniform finite difference grid given by and instance of class [Grid](#).

## Parameters

in	<i>g</i>	<a href="#">Grid</a> instance
in	<i>shape</i>	Value to say which type of elements to generate <ul style="list-style-type: none"> <li>• TRIANGLE: Mesh elements are triangles</li> <li>• QUADRILATERAL: Mesh elements are quadrilaterals [default]</li> </ul>
in	<i>opt</i>	This argument can take any value. It is here only to distinguish from the other constructor using <a href="#">Grid</a> instance.

## Remarks

This constructor is to be used to obtain a dual mesh from a structured grid. It is mainly useful if a cell centered finite volume method is used.

**Mesh ( real\_t xmin, real\_t xmax, size\_t ne, int c1, int c2, int p = 1, size\_t nb\_dof = 1 )**

Constructor for a uniform 1-D finite element mesh.

The domain is the line (xmin,xmax)

## Parameters

in	<i>xmin</i>	Minimal coordinate
in	<i>xmax</i>	Maximal coordinate
in	<i>ne</i>	Number of elements
in	<i>c1</i>	Code for the first node (x=xmin)
in	<i>c2</i>	Code for the last node (x=xmax)
in	<i>p</i>	Degree of approximation polynomial [Default: 1].
in	<i>nb_dof</i>	Number of degrees of freedom per node [Default: 1].

## Remarks

The option p can be set to 1 if the user intends to use finite differences.

**Mesh ( real\_t xmin, real\_t xmax, real\_t ymin, real\_t ymax, size\_t nx, size\_t ny, int cx0, int cxN, int cy0, int cyN, int opt = 0, size\_t nb\_dof = 1 )**

Constructor for a uniform 2-D structured finite element mesh.

The domain is the rectangle (xmin,xmax)x(ymin,ymax)

## Parameters

in	<i>xmin</i>	Minimal x-coordinate
in	<i>xmax</i>	Maximal x-coordinate
in	<i>ymin</i>	Minimal y-coordinate
in	<i>ymax</i>	Maximal y-coordinate
in	<i>nx</i>	Number of subintervals on the x-axis
in	<i>ny</i>	Number of subintervals on the y-axis
in	<i>cx0</i>	Code for nodes generated on the line x=x0 if >0, for sides on this line if <0
in	<i>cxN</i>	Code for nodes generated on the line x=xN if >0, for sides on this line if <0
in	<i>cy0</i>	Code for nodes generated on the line y=y0 if >0, for sides on this line if <0
in	<i>cyN</i>	Code for nodes generated on the line y=yN if >0, for sides on this line if <0
in	<i>opt</i>	Flag to generate elements as well (if not zero) [Default: 0]. If the flag is not 0, it can take one of the enumerated values: TRIANGLE or QUADRILATERAL, with obvious meaning.
in	<i>nb_dof</i>	Number of degrees of freedom per node [Default: 1].

## Remarks

The option opt can be set to 0 if the user intends to use finite differences.

**Mesh ( real.t xmin, real.t xmax, real.t ymin, real.t ymax, real.t zmin, real.t zmax, size.t nx, size.t ny, size.t nz, int cx0, int cxN, int cy0, int cyN, int cz0, int czN, int opt = 0, size.t nb\_dof = 1 )**

Constructor for a uniform 3-D structured finite element mesh.

The domain is the parallepiped (xmin,xmax)x(ymin,ymax)x(zmin,zmax)

Parameters

in	xmin	Minimal x-coordinate
in	xmax	Maximal x-coordinate
in	ymin	Minimal y-coordinate
in	ymax	Maximal y-coordinate
in	zmin	Minimal z-coordinate
in	zmax	Maximal z-coordinate
in	nx	Number of subintervals on the x-axis
in	ny	Number of subintervals on the y-axis
in	nz	Number of subintervals on the z-axis
in	cx0	Code for nodes generated on the line x=xmin if >0, for sides on this line if <0
in	cxN	Code for nodes generated on the line x=xmax if >0, for sides on this line if <0
in	cy0	Code for nodes generated on the line y=ymin if >0, for sides on this line if <0
in	cyN	Code for nodes generated on the line y=ymax if >0, for sides on this line if <0
in	cz0	Code for nodes generated on the line z=zmin if >0, for sides on this line if <0
in	czN	Code for nodes generated on the line z=zmax if >0, for sides on this line if <0
in	opt	Flag to generate elements as well (if not zero) [Default: 0]. If the flag is not 0, it can take one of the enumerated values: HEXAHEDRON or TETRAHEDRON, with obvious meaning.
in	nb_dof	Number of degrees of freedom per node [Default: 1].

Remarks

The option opt can be set to 0 if the user intends to use finite differences.

**Mesh ( const Mesh & m, const Point< real.t > & x\_bl, const Point< real.t > & x\_tr )**

Constructor that extracts the mesh of a rectangular region from an initial mesh.

This constructor is useful for zooming purposes for instance.

Parameters

in	m	Initial mesh from which the submesh is extracted
in	x_bl	Coordinate of bottom left vertex of the rectangle
in	x_tr	Coordinate of top right vertex of the rectangle

**Mesh ( const Mesh & mesh, int opt, size.t dof1, size.t dof2, bool bc = false )**

Constructor that copies the input mesh and selects given degrees of freedom.

This constructor is to be used for coupled problems where each subproblem uses a choice of degrees of freedom.

Parameters

in	<i>mesh</i>	Initial mesh from which the submesh is extracted
in	<i>opt</i>	Type of DOF support: To choose among enumerated values NO↔DE_DOF, SIDE_DOF or ELEMENT_DOF.
in	<i>dof1</i>	Label of first degree of freedom to select to the output mesh
in	<i>dof2</i>	Label of last degree of freedom to select to the output mesh
in	<i>bc</i>	Flag to remove (true) or not (false) imposed Degrees of Freedom [Default: false]

**Mesh ( const Mesh & *ms* )**

Copy Constructor.

Parameters

in	<i>ms</i>	<a href="#">Mesh</a> instance to copy
----	-----------	---------------------------------------

### 7.71.3 Member Function Documentation

**void setDim ( size\_t *dim* )**

Define space dimension. Normally, between 1 and 3.

Parameters

in	<i>dim</i>	Space dimension to set (must be between 1 and 3)
----	------------	--

**void Add ( Node \* *nd* )**

Add a node to mesh.

Parameters

in	<i>nd</i>	Pointer to <a href="#">Node</a> to add
----	-----------	--

**void Add ( Element \* *el* )**

Add an element to mesh.

Parameters

in	<i>el</i>	Pointer to <a href="#">Element</a> to add
----	-----------	---

**void Add ( Side \* *sd* )**

Add a side to mesh.

Parameters

in	<i>sd</i>	Pointer to <a href="#">Side</a> to add
----	-----------	--

**void Add ( Edge \* *ed* )**

Add an edge to mesh.

Parameters

<code>in</code>	<code>ed</code>	Pointer to <a href="#">Edge</a> to add
-----------------	-----------------	--

**Mesh& operator\*= ( real\_t a )**

Operator \*=

Rescale mesh coordinates by multiplying by a factor

Parameters

<code>in</code>	<code>a</code>	Value to multiply by
-----------------	----------------	----------------------

**void get ( const string & mesh\_file )**

Read mesh data in file.

[Mesh](#) file must be in [OFELI](#) format. See "File Formats" page

Parameters

<code>in</code>	<code>mesh_file</code>	<a href="#">Mesh</a> file name
-----------------	------------------------	--------------------------------

**void get ( const string & mesh\_file, int ff, int nb\_dof = 1 )**

Read mesh data in file with giving its format.

File format can be chosen among a variety of choices. See "File Formats" page

Parameters

<code>in</code>	<code>mesh_file</code>	<a href="#">Mesh</a> file name
<code>in</code>	<code>ff</code>	File format: Integer to chose among enumerated values: <a href="#">OFELI_FF</a> , <a href="#">GMSH</a> , <a href="#">MATLAB</a> , <a href="#">EASYMESH</a> , <a href="#">GAMBIT</a> , <a href="#">BAMG</a> , <a href="#">NETGEN</a> , <a href="#">TRIANGLE_FF</a>
<code>in</code>	<code>nb_dof</code>	Number of degrees of freedom per node (Default value: 1)

**void setDOFSupport ( int opt, int nb\_nodes = 1 )**

Define supports of degrees of freedom.

Parameters

<code>in</code>	<code>opt</code>	DOF type: <ul style="list-style-type: none"> <li>• <a href="#">NODE_DOF</a>: Degrees of freedom are supported by nodes</li> <li>• <a href="#">SIDE_DOF</a>: Degrees of freedom are supported by sides</li> <li>• <a href="#">EDGE_DOF</a>: Degrees of freedom are supported by edges</li> <li>• <a href="#">ELEMENT_DOF</a>: Degrees of freedom are supported by elements</li> </ul>
-----------------	------------------	--

<b>in</b>	<i>nb_nodes</i>	Number of nodes on sides or elements (default=1). This parameter is useful only if dofs are supported by sides or elements
-----------	-----------------	--

**Note**

This member function creates all mesh sides if the option `ELEMENT_DOF` or `SIDE_DOF` is selected. So it not necessary to call [getAllSides\(\)](#) after

**void setNbDOFPerNode ( size\_t nb\_dof = 1 )**

Define number of degrees of freedom for each node.

Parameters

<b>in</b>	<i>nb_dof</i>	Number of degrees of freedom (unknowns) for each mesh node (Default value is 1)
-----------	---------------	---

**Note**

This function first declares nodes as unknown supports, sets the number of degrees of freedom and renumbers equations

**void setPointInDomain ( Point< real\_t > x )**

Define a point in the domain. This function makes sense only if boundary mesh is given without internal mesh (Case of Boundary Elements)

Parameters

<b>in</b>	<i>x</i>	Coordinates of point to define
-----------	----------	--------------------------------

**size\_t NumberEquations ( size\_t dof = 0 )**

Renumber Equations.

Parameters

<b>in</b>	<i>dof</i>	Label of degree of freedom for which numbering is performed. Default value (0) means that all degrees of freedom are taken into account
-----------	------------	---

**size\_t NumberEquations ( size\_t dof, int c )**

Renumber Equations.

Parameters

<b>in</b>	<i>dof</i>	Label of degree of freedom for which numbering is performed.
<b>in</b>	<i>c</i>	code for which degrees of freedom are enforced.

**int getAllSides ( int opt = 0 )**

Determine all mesh sides.

Returns

Number of all sides.

**int getBoundarySides ( )**

Determine all boundary sides.

Returns

Number of boundary sides.

**int createBoundarySideList ( )**

Create list of boundary sides.

This function is useful to loop over boundary sides without testing Once this one is called, the function [getNbBoundarySides\(\)](#) is available. Moreover, looping over boundary sides is available via the member functions [topBoundarySide\(\)](#) and [getBoundarySide\(\)](#)

Returns

Number of boundary sides.

**int getBoundaryNodes ( )**

Determine all boundary nodes.

Returns

n Number of boundary nodes.

**int createInternalSideList ( )**

Create list of internal sides (not on the boundary).

This function is useful to loop over internal sides without testing Once this one is called, the function [getNbInternalSides\(\)](#) is available. Moreover, looping over internal sides is available via the member functions [topInternalSide\(\)](#) and [getInternalSide\(\)](#)

Returns

n Number of internal sides.

**int getAllEdges ( )**

Determine all edges.

Returns

Number of all edges.

**void getNodeNeighborElements ( )**

Create node neighboring elements.

This function is generally useful when, for a numerical method, one looks for a given node to the list of elements that share this node. Once this function is invoked, one can retrieve the list of neighboring elements of any node ([Node::getNeigEl](#))

**void getElementNeighborElements ( )**

Create element neighboring elements.

This function creates for each element the list of elements that share a side with it. Once this function is invoked, one can retrieve the list of neighboring elements of any element (`Element↵::getElement`)

**void setMaterial ( int *code*, const string & *mname* )**

Associate material to code of element.

Parameters

<b>in</b>	<i>code</i>	<a href="#">Element</a> code for which material is assigned
<b>in</b>	<i>mname</i>	Name of material

**void Reorder ( size\_t *m* = GRAPH\_MEMORY )**

Renumber mesh nodes according to reverse Cuthill Mc Kee algorithm.

Parameters

<b>in</b>	<i>m</i>	Memory size needed for matrix graph (default value is GRAPH_MEMORY, see OFELI_Config.h)
-----------	----------	---

**void Add ( size\_t *num*, real\_t \* *x* )**

Add a node by giving its label and an array containing its coordinates.

Parameters

<b>in</b>	<i>num</i>	Label of node to add
<b>in</b>	<i>x</i>	C-array of node coordinates

**void DeleteNode ( size\_t *label* )**

Remove a node given by its label.

This function does not release the space previously occupied

Parameters

<b>in</b>	<i>label</i>	Label of node to delete
-----------	--------------	-------------------------

**void DeleteElement ( size\_t *label* )**

Remove an element given by its label.

This function does not release the space previously occupied

Parameters

<b>in</b>	<i>label</i>	Label of element to delete
-----------	--------------	----------------------------

**void DeleteSide ( size\_t *label* )**

Remove a side given by its label.

This function does not release the space previously occupied

Parameters

<b>in</b>	<i>label</i>	Label of side to delete
-----------	--------------	-------------------------

**void Delete ( Node \* *nd* )**

Remove a node given by its pointer.

This function does not release the space previously occupied

Parameters

<b>in</b>	<i>nd</i>	Pointer to node to delete
-----------	-----------	---------------------------

**void Delete ( Element \* *el* )**

Remove a node given by its pointer.

This function does not release the space previously occupied

Parameters

<b>in</b>	<i>el</i>	Pointer to element to delete
-----------	-----------	------------------------------

**void Delete ( Side \* *sd* )**

Remove a side given by its pointer.

This function does not release the space previously occupied

Parameters

<b>in</b>	<i>sd</i>	Pointer to side to delete
-----------	-----------	---------------------------

**void Delete ( Edge \* *ed* )**

Remove an edge given by its pointer.

This function does not release the space previously occupied

Parameters

<b>in</b>	<i>ed</i>	Pointer to edge to delete
-----------	-----------	---------------------------

**void RenumberNode ( size\_t *n1*, size\_t *n2* )**

Renumber a node.

Parameters

<b>in</b>	<i>n1</i>	Old label
<b>in</b>	<i>n2</i>	New label

**void RenumberElement ( size\_t *n1*, size\_t *n2* )**

Renumber an element.

Parameters

<b>in</b>	<i>n1</i>	Old label
<b>in</b>	<i>n2</i>	New label

**void RenumberSide ( size\_t *n1*, size\_t *n2* )**

Renumber a side.

Parameters

<b>in</b>	<i>n1</i>	Old label
<b>in</b>	<i>n2</i>	New label

**void RenumberEdge ( size\_t *n1*, size\_t *n2* )**

Renumber an edge.

Parameters

<b>in</b>	<i>n1</i>	Old label
<b>in</b>	<i>n2</i>	New label

**void setList ( const std::vector< Node \* > & *nl* )**

Initialize list of mesh nodes using the input vector.

Parameters

<b>in</b>	<i>nl</i>	vector instance that contains the list of pointers to nodes
-----------	-----------	---

**void setList ( const std::vector< Element \* > & *el* )**

Initialize list of mesh elements using the input vector.

Parameters

<b>in</b>	<i>el</i>	vector instance that contains the list of pointers to elements
-----------	-----------	--

**void setList ( const std::vector< Side \* > & *sl* )**

Initialize list of mesh sides using the input vector.

Parameters

<b>in</b>	<i>sl</i>	vector instance that contains the list of pointers to sides
-----------	-----------	---

**void Rescale ( real\_t *sx*, real\_t *sy* = 0., real\_t *sz* = 0. )**

Rescale mesh by multiplying node coordinates by constants.

This function can be used e.g. for changing coordinate units

Parameters

<b>in</b>	<i>sx</i>	Factor to multiply by x coordinates
<b>in</b>	<i>sy</i>	Factor to multiply by y coordinates [Default: <i>sx</i> ]
<b>in</b>	<i>sz</i>	Factor to multiply by z coordinates [Default: <i>sx</i> ]

**size\_t getNbBoundarySides ( ) const**

Return number of boundary sides.

This function is valid if member function **getAllSides** or **getBoundarySides** has been invoked before

**size\_t getNbInternalSides ( ) const**

Return number of internal sides.

This function is valid if member functions **getAllSides** and **createInternalSideList** have been invoked before

**void AddMidNodes ( int *g* = 0 )**

Add mid-side nodes.

This is function is valid for triangles only

Parameters

in	<i>g</i>	Option to say of barycentre node is to be added (>0) or not (=0)
----	----------	--

**void set ( Node \* *nd* )**

Replace node in the mesh.

If the node label exists already, the existing node pointer will be replaced by the current one. If not, an error message is displayed.

Parameters

in	<i>nd</i>	Pointer to node
----	-----------	-----------------

**void set ( Element \* *el* )**

Replace element in the mesh.

If the element label exists already, the existing element pointer will be replaced by the current one. If not, an error message is displayed.

Parameters

in	<i>el</i>	Pointer to element
----	-----------	--------------------

**void set ( Side \* *sd* )**

Choose side in the mesh.

If the side label exists already, the existing side pointer will be replaced by the current one. If not, an error message is displayed.

Parameters

in	<i>sd</i>	Pointer to side
----	-----------	-----------------

**bool NodesAreDOF ( ) const**

Return information about DOF type.

Returns

true if DOF are supported by nodes, false otherwise

**bool SidesAreDOF ( ) const**

Return information about DOF type.

Returns

true if DOF are supported by sides, false otherwise

**bool EdgesAreDOF ( ) const**

Return information about DOF type.

Returns

true if DOF are supported by edges, false otherwise

**bool ElementsAreDOF ( ) const**

Return information about DOF type.

Returns

true if DOF are supported by elements, false otherwise

**void Deform ( const Vect< real\_t > & u, real\_t rate = 0.2 )**

Deform mesh according to a displacement vector.

This function modifies node coordinates according to given displacement vector and given rate

Parameters

in	<i>u</i>	Displacement vector
in	<i>rate</i>	Maximal rate of deformation of resulting mesh. Its default value is 0.2, <i>i.e.</i> The resulting mesh has a maximum of deformation rate of 20%

**void put ( const string & mesh\_file ) const**

Write mesh data on file.

Parameters

in	<i>mesh_file</i>	Mesh file name
----	------------------	----------------

**void save ( const string & mesh\_file ) const**

Write mesh data on file in various formats.

File format depends on the extension in file name

Parameters

in	<i>mesh_file</i>	Mesh file name If the extension is '.m', the output file is an <a href="#">OF↵ELI</a> file If the extension is '.gpl', the output file is a Gnuplot file If the extension is '.msh' or '.geo', the output file is a Gmsh file If the extension is '.vtk', the output file is a VTK file
----	------------------	---

**void getList ( vector< Node \* > & nl ) const**

Fill vector nl with list of pointers to nodes.

Parameters

out	<i>nl</i>	Instance of class vector that contain on output the list
-----	-----------	--

**void getList ( vector< Element \* > & *el* ) const**

Fill vector *el* with list of pointers to elements.

Parameters

out	<i>el</i>	Instance of class vector that contain on output the list
-----	-----------	--

**void getList ( vector< Side \* > & *sl* ) const**

Fill vector *sl* with list of pointers to sides.

Parameters

out	<i>sl</i>	Instance of class vector that contain on output the list
-----	-----------	--

**size\_t getNodeLabel ( size\_t *i* ) const**

Return label of *i*-th node.

Parameters

in	<i>i</i>	<a href="#">Node</a> index
----	----------	----------------------------

**size\_t getElementLabel ( size\_t *i* ) const**

Return label of *i*-th element.

Parameters

in	<i>i</i>	<a href="#">Element</a> index
----	----------	-------------------------------

**size\_t getSideLabel ( size\_t *i* ) const**

Return label of *i*-th side.

Parameters

in	<i>i</i>	<a href="#">Side</a> index
----	----------	----------------------------

**size\_t getEdgeLabel ( size\_t *i* ) const**

Return label of *i*-th edge.

Parameters

in	<i>i</i>	<a href="#">Edge</a> index
----	----------	----------------------------

**Element\* getActiveElement ( ) const**

Return pointer to current element and move to next one (Non constant version)

This function returns pointer to the current element only if this one is active. Otherwise it goes to the next active element (To be used when adaptive meshing is involved)

#### 7.71.4 Friends And Related Function Documentation

**void Refine ( Mesh & *in\_mesh*, Mesh & *out\_mesh* )** [friend]

Refine mesh. Subdivide each triangle into 4 subtriangles. This member function is valid for 2-D triangular meshes only.

Parameters

in	in_mesh	Input mesh
out	out_mesh	Output mesh

## 7.72 MeshAdapt Class Reference

To adapt mesh in function of given solution.

### 7.72.1 Detailed Description

To adapt mesh in function of given solution.

Class `MeshAdapt` enables modifying mesh according to a solution vector defining at nodes. It concerns 2-D triangular meshes only.

Remarks

Class `MeshAdapt` is mainly based on the software 'Bamg' developed by F. Hecht, Universite Pierre et Marie Curie, Paris. We warmly thank him for accepting incorporation of Bamg in the `OFELI` package

Author

Rachid Touzani

GNU Lesser Public License

### 7.72.2 Constructor & Destructor Documentation

**MeshAdapt ( Mesh & ms )**

Constructor using initial mesh.

Parameters

<code>in</code>	<code>ms</code>	Reference to initial mesh
-----------------	-----------------	---------------------------

**MeshAdapt ( Domain & dom )**

Constructor using a reference to class `Domain`.

Parameters

<code>in</code>	<code>dom</code>	Reference to <code>Domain</code> class
-----------------	------------------	--

### 7.72.3 Member Function Documentation

**void setRelaxation ( real\_t omega )**

Set relaxation parameter for smoothing.

Default value for relaxation parameter is 1.8

**void setMaxNbVertices ( size\_t *n* )**

Set maximum number of vertices.

Default value is 500000

**void setRatio ( real\_t *r* )**

Set ratio for a smoothing of the metric.

Parameters

<i>in</i>	<i>r</i>	Ratio value.
-----------	----------	--------------

Note

If *r* is 0 then no smoothing is performed, if *r* lies in  $[1, 10]$  then the smoothing changes the metric such that the largest geometrical progression (speed of mesh size variation in mesh is bounded by *r*) (by default no smoothing)

**void setNoScaling ( )**

Do not scale solution before metric computation.

By default, solution is scaled (between 0 and 1)

**void setNoKeep ( )**

Do not keep old vertices.

By default, old vertices are kept

**void getSolutionbb ( string *rbb* )**

Read solution defined on the background mesh in bb file.

Solution is interpolated on created mesh

**void getSolutionBB ( string *rBB* )**

Read solution defined on the background mesh in BB file.

Solution is interpolated on created mesh

**void getSolution ( Vect< real\_t > &*u*, int *is* = 1 )**

Get the interpolated solution on the new mesh.

The solution must have been saved on an output bb file

Parameters

<i>out</i>	<i>u</i>	Vector that contains on output the obtained solutions. This vector is resized before being initialized
<i>in</i>	<i>is</i>	[Default: 1]

**void setTheta ( real\_t *theta* )**

Set angular limit for a corner (in degrees)

The angle is defined from 2 normals of 2 consecutive edges

**void saveMbb ( string *file*, const Vect< real\_t > &*u* )**

Save a solution in metric file.

Parameters

<b>in</b>	<i>file</i>	File name where the metric is stored
<b>in</b>	<i>u</i>	Solution vector to store

**int run ( )**

Run adaptation process.

Returns

Return code:

- = 0: Adaptation has been normally completed
- = 1: An error occurred

**int run ( const Vect< real\_t > &u )**

Run adaptation process using a solution vector.

Parameters

<b>in</b>	<i>u</i>	Solution vector defined on the input mesh
-----------	----------	---

Returns

Return code:

- = 0: Adaptation has been normally completed
- = 1: An error occurred

**int run ( const Vect< real\_t > &u, Vect< real\_t > &v )**

Run adaptation process using a solution vector and interpolates solution on the adapted mesh.

Parameters

<b>in</b>	<i>u</i>	Solution vector defined on the input mesh
<b>in</b>	<i>v</i>	Solution vector defined on the (adapted) output mesh

Returns

Return code:

- = 0: Adaptation has been normally completed
- = 1: An error occurred

### 7.73.2 Member Enumeration Documentation

**enum Method**

Enumeration for flux choice.

Enumerator

`FIRST_ORDER_METHOD` First Order upwind method

`MULTI_SLOPE_Q_METHOD` Multislope Q method

`MULTI_SLOPE_M_METHOD` Multislope M method

**enum Limiter**

Enumeration of flux limiting methods.

Enumerator

*MINMOD\_LIMITER* MinMod limiter  
*VANLEER\_LIMITER* Van Leer limiter  
*SUPERBEE\_LIMITER* Superbee limiter  
*VANALBADA\_LIMITER* Van Albada limiter  
*MAX\_LIMITER* Max limiter

**enum SolverType**

Enumeration of various solvers for the Riemann problem.

Enumerator

*ROE\_SOLVER* Roe solver  
*VROE\_SOLVER* Finite Volume Roe solver  
*LF\_SOLVER* LF solver  
*RUSANOV\_SOLVER* Rusanov solver  
*HLL\_SOLVER* HLL solver  
*HLLC\_SOLVER* HLLC solver  
*MAX\_SOLVER* Max solver

**7.73.3 Member Function Documentation****void setTimeStep ( real.t *dt* )**

Assign time step value.

Parameters

in	<i>dt</i>	Time step value
----	-----------	-----------------

**void setCFL ( real.t *CFL* )**

Assign CFL value.

Parameters

in	<i>CFL</i>	Value of CFL
----	------------	--------------

**void setReferenceLength ( real.t *dx* )**

Assign reference length value.

Parameters

in	$dx$	Value of reference length
----	------	---------------------------

**void setVerbose ( int  $v$  )**

Set verbosity parameter.

Parameters

in	$v$	Value of verbosity parameter
----	-----	------------------------------

**bool setReconstruction ( const Vect< real.t > &  $U$ , Vect< real.t > &  $LU$ , Vect< real.t > &  $RU$ , size.t  $dof$  )**

Function to reconstruct by the [Muscl](#) method.

Parameters

in	$U$	Field to reconstruct
out	$LU$	Left gradient vector
out	$RU$	Right gradient vector
in	$dof$	Label of dof to reconstruct

**void setMethod ( const Method &  $s$  )**

Choose a flux solver.

Parameters

in	$s$	Solver to choose
----	-----	------------------

**void setLimiter ( Limiter  $l$  )**

Choose a flux limiter.

Parameters

in	$l$	Limiter to choose
----	-----	-------------------

### 7.75.2 Member Function Documentation

**bool setReconstruction ( const [Vect< real.t >](#) &U, [Vect< real.t >](#) &LU, [Vect< real.t >](#) &RU, size\_t dof )**

Function to reconstruct by the [Muscl](#) method.

Parameters

in	$U$	Field to reconstruct
out	$LU$	Left gradient vector
out	$RU$	Right gradient vector
in	$dof$	Label of dof to reconstruct

**void Initialize ( )** [protected]

Construction of normals to sides.

Convention: for a given side, `getPtrElement(1)` is the left element and `getPtrElement(2)` is the right element. The normal goes from left to right. For boundary sides, the normal points outward.

### 7.77.1 Detailed Description

Abstract class to define by user specified function.

The user has to implement a class that inherits from the present one where the virtual functions are implemented.

Author

Rachid Touzani

Copyright

GNU Lesser Public License

### 7.77.2 Constructor & Destructor Documentation

**MyNLAS** ( `const Mesh & mesh` )

Constructor using mesh instance.

Parameters

<code>mesh</code>	Reference to <a href="#">Mesh</a> instance
-------------------	--

### 7.77.3 Member Function Documentation

**virtual real\_t Function** ( `const Vect< real_t > & x, int i = 1` ) [pure virtual]

Virtual member function to define nonlinear function to zeroe.

Parameters

<code>in</code>	<code>x</code>	Vector of variables
<code>in</code>	<code>i</code>	component of function to define [Default: 1].

Returns

Value of function

Warning

The component must not be larger than vector size

**virtual real\_t Gradient** ( `const Vect< real_t > & x, int i = 1, int j = 1` ) [virtual]

Virtual member function to define partial derivatives of function.

Parameters

<code>in</code>	<code>x</code>	Vector of variables
<code>in</code>	<code>i</code>	Function component [Default: 1]
<code>in</code>	<code>j</code>	Index of partial derivative [Default: 1]

Returns

Value of partial derivative

GNU Lesser Public License

### 7.78.2 Constructor & Destructor Documentation

**MyOpt ( Mesh & mesh )**

Constructor using mesh instance.

Parameters

<i>mesh</i>	Reference to <a href="#">Mesh</a> instance
-------------	--

### 7.78.3 Member Function Documentation

**virtual real\_t Objective ( Vect< real\_t > &x ) [pure virtual]**

Virtual member function to define objective.

Parameters

in	<i>x</i>	Vector of optimization variables
----	----------	----------------------------------

Returns

Value of objective

**virtual void Gradient ( Vect< real\_t > &x, Vect< real\_t > &g ) [virtual]**

Virtual member function to define gradient vector of objective.

Parameters

in	$x$	Vector of optimization variables
out	$g$	Gradient vector

**void setEquation ( Equa \* eq )**

Define equation instance.

Parameters

in	eq	Pointer to equation instance
----	----	------------------------------

Remarks

This member function is to be invoked in the user class defining the optimization problem

**Equa\* getEquation ( ) const**

Get pointer to equation instance.

Returns

Pointer to equation instance

### 7.79.1 Detailed Description

To solve a system of nonlinear algebraic equations of the form  $f(u) = 0$ .

Features:

- The nonlinear problem is solved by the Newton's method in the general case, and in the one variable case, either by the bisection or the Regula Falsi method
- The function and its gradient are given:
  - Either by regular expressions
  - Or by user defined functions
  - Or by a user defined class. This feature enables defining the function and its gradient through a PDE class for instance

### 7.79.2 Constructor & Destructor Documentation

**NLA Solver** ( **NonLinearIter** nl, int nb\_eq = 1 )

Constructor defining the iterative method to solve the equation.

Parameters

in	<i>nl</i>	Choose an iterative procedure to solve the nonlinear system of equations: To be chosen among the enumerated values: BISECTION, REGULA_FALSI or NEWTON.
in	<i>nb_eq</i>	Number of equations [Default: 1]

**NLASSolver ( real\_t & x, NonLinearIter nl = NEWTON )**

Constructor defining a one-variable problem.

Parameters

in	<i>x</i>	Variable containing on input initial guess and on output solution, if convergence is achieved
in	<i>nl</i>	Iterative procedure to solve the nonlinear system of equations: To be chosen among the enumerated values: BISECTION, REGULA_FALSI or NEWTON.

**NLASSolver ( Vect< real\_t > & x, NonLinearIter nl = NEWTON )**

Constructor defining a multi-variable problem.

Parameters

in	<i>x</i>	Variable containing on input initial guess and on output solution, if convergence is achieved
in	<i>nl</i>	Iterative procedure to solve the nonlinear system of equations: The only possible value (default one) in the current version is NEWTON.

**NLASSolver ( MyNLAS & my\_nlas, NonLinearIter nl = NEWTON )**

Constructor using a user defined class.

Parameters

in	<i>my_nlas</i>	Reference to instance of user defined class. This class inherits from abstract class <a href="#">MyNLAS</a> . It must contain the member function Vect<double> Function(const Vect<double>& x) which returns the value of the nonlinear function, as a vector, for a given solution vector x. The user defined class must contain, if the iterative scheme requires it the member function Vect<double> Gradient(const Vect<real_t>& x) which returns the gradient as a n*n vector, each index (i,j) containing the j-th partial derivative of the i-th function.
----	----------------	---

<code>in</code>	<code>nl</code>	Iterative procedure to solve the nonlinear system of equations: To be chosen among the enumerated values: <code>BISECTION</code> , <code>REGULA_FALSI</code> or <code>NEWTON</code> .
-----------------	-----------------	---

### 7.79.3 Member Function Documentation

**void setMaxIter ( int *max\_it* )**

Set Maximal number of iterations.

Default value of this parameter is 100

**void setTolerance ( real\_t *toler* )**

Set tolerance value for convergence.

Default value of this parameter is 1.e-8

**void setFunction ( function< real\_t(real\_t)> *f* )**

Define the function associated to the equation to solve.

This function can be used in the case where a user defined function is to be given. To be used in the one-variable case.

Parameters

<code>in</code>	<code>f</code>	Function given as a function of one real variable and returning a real number. This function can be defined by the calling program as a C-function and then cast to an instance of class function
-----------------	----------------	---

**void setFunction ( function< Vect< real\_t >(Vect< real\_t >)> *f* )**

Define the function associated to the equation to solve.

This function can be used in the case where a user defined function is to be given.

Parameters

<code>in</code>	<code>f</code>	Function given as a function of many variables, stored in an input vector, and returns a vector. This function can be defined by the calling program as a C-function and then cast to an instance of class function
-----------------	----------------	---

**void setGradient ( function< real\_t(real\_t)> *g* )**

Define the function associated to the derivative of the equation to solve.

Parameters

<code>in</code>	<code>g</code>	Function given as a function of one real variable and returning a real number. This function can be defined by the calling program as a C-function and then cast to an instance of class function
-----------------	----------------	---

**void setGradient ( function< Vect< real\_t >(Vect< real\_t >)> *g* )**

Define the function associated to the gradient of the equation to solve.

Parameters

in	<i>g</i>	Function given as a function of many variables, stored in an input vector. and returns a $n \times n$ vector ( $n$ is the number of variables). This function can be defined by the calling program as a C-function and then cast to an instance of class function
----	----------	--

**void setf ( string *exp* )**

Set function for which zero is sought (case of one equation)

Parameters

in	<i>exp</i>	Regular expression defining the function using the symbol $x$ as a variable
----	------------	---

**void setDf ( string *exp*, int *i* = 1, int *j* = 1 )**

Set pztial derivative of function for which zero is sought (case of many equations)

Parameters

in	<i>exp</i>	Regular expression defining the partial derivative. In this expression, the variables are $x_1, x_2, \dots, x_{10}$ (up to 10 variables)
in	<i>i</i>	Component of function [Default: =1]
in	<i>j</i>	Index of the partial derivative [Default: =1]

**void setPDE ( Equa & *eq* )**

Define a PDE.

The solver can be used to solve a nonlinear PDE. In this case, the PDE is defined as an instance of a class inheriting of [Equa](#).

Parameters

in	<i>eq</i>	Pointer to equation instance
----	-----------	------------------------------

**void setInitial ( Vect< real\_t > & *u* )**

Set initial guess for the iterations.

Parameters

in	<i>u</i>	Vector containing initial guess for the unknown
----	----------	---

**void setInitial ( real\_t & *x* )**

Set initial guess for a unique unknown.

Parameters

in	<i>x</i>	Rference to value of initial guess
----	----------	------------------------------------

**void setInitial ( real\_t *a*, real\_t *b* )**

Set initial guesses bisection or Regula falsi algorithms.

Parameters

in	$a$	Value of first initial guess
in	$b$	Value of second initial guess

Note

The function has to have opposite signs at these values i.e.  $f(a)f(b) < 0$ .

Warning

This function makes sense only in the case of a unique function of one variable

**void get ( Vect< real.t > &u ) const**

Return solution (case of a nonlinear system of equations)

Parameters

out	$u$	Vector that contains on output the solution
-----	-----	---

  - int **getLevel** () const
- Return node level.*

### 7.80.1 Detailed Description

To describe a node.

A node is characterized by its label, its coordinates, its number of degrees of freedom (DOF) and codes that are associated to each DOF.

Remarks

Once the mesh is constructed, information on neighboring elements of node can be retrieved (see appropriate member functions). However, the member function `getNode↵NeighborElements` of `Mesh` must have been called before. If this is not the case, the program crashes down since no preliminary checking is done for efficiency reasons.

### 7.80.2 Constructor & Destructor Documentation

**Node ( )**

Default constructor.

Initialize data to zero

**Node ( *size.t label*, *const Point< real.t > & x* )**

Constructor with label and coordinates.

Parameters

<i>in</i>	<i>label</i>	Label of node
<i>in</i>	<i>x</i>	Node coordinates

### 7.80.3 Member Function Documentation

**void setCode ( *size.t dof*, *int code* )**

Define code for a given DOF of node.

Parameters

<i>in</i>	<i>dof</i>	DOF index
<i>in</i>	<i>code</i>	Code to assign to DOF

**void setCode ( *const vector< int > & code* )**

Define codes for all node DOFs.

Parameters

<i>in</i>	<i>code</i>	vector instance that contains code for each DOF of current node
-----------	-------------	---

**void setCode ( *int \* code* )**

Define codes for all node DOFs.

Parameters

<i>in</i>	<i>code</i>	C-array that contains code for each DOF of current node
-----------	-------------	---

**void setCode ( *const string & exp*, *int code*, *size.t dof = 1* )**

Define code by a boolean algebraic expression invoking node coordinates.

Parameters

<b>in</b>	<i>exp</i>	Boolean algebraic expression as required by <code>fparser</code>
<b>in</b>	<i>code</i>	Code to assign to node if the algebraic expression is true
<b>in</b>	<i>dof</i>	Degree of Freedom for which code is assigned [Default: 1]

**void setCoord ( size\_t *i*, real\_t *x* )**

Set *i*-th coordinate.

Parameters

<b>in</b>	<i>i</i>	Coordinate index (1..3)
<b>in</b>	<i>x</i>	Coordinate value

**void DOF ( size\_t *i*, size\_t *dof* )**

Define label of DOF.

Parameters

<b>in</b>	<i>i</i>	DOF index
<b>in</b>	<i>dof</i>	Label of DOF

**void setDOF ( size\_t &*first\_dof*, size\_t *nb\_dof* )**

Define number of DOF.

Parameters

<b>in,out</b>	<i>first_dof</i>	Label of the first DOF in input that is actualized
<b>in</b>	<i>nb_dof</i>	Number of DOF

**void setOnBoundary ( )**

Set node as boundary node.

This function is mostly internally used (Especially in class [Mesh](#))

**int getCode ( size\_t *dof* = 1 ) const**

Return code for a given DOF of node.

Parameters

<b>in</b>	<i>dof</i>	label of degree of freedom for which code is to be returned. Default value is 1.
-----------	------------	--

**Point<real\_t> getCoord ( ) const**

Return coordinates of node.

Return value is an instance of class [Point](#)

**Point<real\_t> getXYZ ( ) const**

Return coordinates of node.

Return value is an instance of class [Point](#)

**size\_t getNbNeigEl ( ) const**

Return number of neighbor elements.

Neighbor elements are those that share node. Note that the returned information is valid only if the [Mesh](#) member function **getNodeNeighborElements()** has been invoked before

**Element\* getNeigEl ( size\_t i ) const**

Return i-th neighbor element.

Note that the returned information is valid only if the [Mesh](#) member function **getNodeNeighborElements()** has been invoked before

**bool isOnBoundary ( ) const**

Say if node is a boundary node.

Note this information is available only if boundary sides (and nodes) were determined (See class [Mesh](#)).

**void setLevel ( int level )**

Assign a level to current node.

This member function is useful for mesh adaption.  
Default node's level is zero

**int getLevel ( ) const**

Return node level.

[Node](#) level decreases when element is refined (starting from 0). If the level is 0, then the element has no parents

## 7.81 NodeList Class Reference

Class to construct a list of nodes having some common properties.

### Public Member Functions

- `Node * get () const`

*Return pointer to current node and move to next one (Constant version)*

### 7.81.1 Detailed Description

Class to construct a list of nodes having some common properties.

This class enables choosing multiple selection criteria by using function `select...`. However, the intersection of these properties must be empty.

Author

Rachid Touzani

Copyright

GNU Lesser Public License

### 7.81.2 Member Function Documentation

**void selectCode ( int code, int dof = 1 )**

Select nodes having a given code for a given degree of freedom.

Parameters

in	code	Code that nodes share
in	dof	Degree of Freedom label [Default: 1]

**void unselectCode ( int code, int dof = 1 )**

Unselect nodes having a given code for a given degree of freedom.

Parameters

in	code	Code of nodes to exclude
in	dof	Degree of Freedom label [Default: 1]

**void selectCoordinate ( real.t x, real.t y = ANY, real.t z = ANY )**

Select nodes having given coordinates.

Parameters

in	x	x-coordinate that share the selected nodes
in	y	y-coordinate that share the selected nodes [Default: ANY]
in	z	z-coordinate that share the selected nodes [Default: ANY]

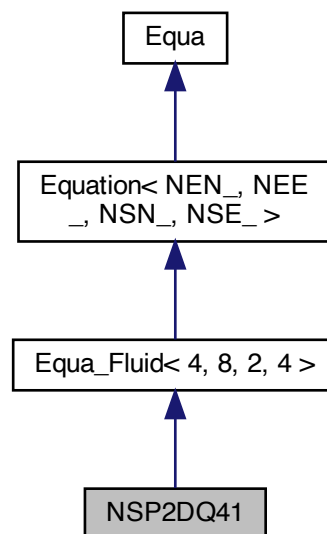

Coordinates can be assigned the value ANY. This means that any coordinate value is accepted. For instance, to select all nodes with x=0, use `selectCoordinate(0.,ANY,ANY)`;

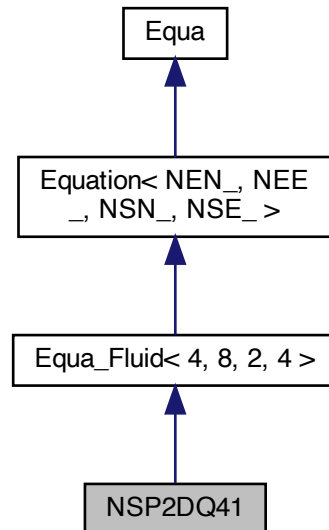

## 7.82 NSP2DQ41 Class Reference

Builds finite element arrays for incompressible Navier-Stokes equations in 2-D domains using  $Q_1/P_0$  element and a penalty formulation for the incompressibility condition.

## 7.82.2 Constructor & Destructor Documentation

### NSP2DQ41 ( Mesh & *ms* )

Constructor using mesh data.

Parameters

<i>in</i>	<i>ms</i>	<a href="#">Mesh</a> instance
-----------	-----------	-------------------------------

### NSP2DQ41 ( Mesh & *ms*, Vect< real\_t > & *u* )

Constructor using mesh data and velocity vector.

Parameters

<i>in</i>	<i>ms</i>	<a href="#">Mesh</a> instance
<i>in</i> , <i>out</i>	<i>u</i>	Velocity vector

## 7.82.3 Member Function Documentation

### void setPenalty ( real\_t *lambda* )

Define penalty parameter.

Penalty parameter is used to enforce the incompressibility constraint

Parameters

<i>in</i>	<i>lambda</i>	Penalty parameter: Large value [Default: 1.e07]
-----------	---------------	---

### void setInput ( EqDataType *opt*, Vect< real\_t > & *u* )

Set equation input data.

Parameters

<i>in</i>	<i>opt</i>	Parameter that selects data type for input. This parameter is to be chosen in the enumerated variable EqDataType
<i>in</i>	<i>u</i>	<a href="#">Vect</a> instance that contains input vector data List of data types contains INITIAL_FIELD, BOUNDARY_CONDITION.DATA, SOURCE_DATA or FLUX with obvious meaning

### void Periodic ( real\_t *coef* = 1.e20 )

Add contribution of periodic boundary condition (by a penalty technique).

Boundary nodes where periodic boundary conditions are to be imposed must have codes equal to PERIODIC.A on one side and PERIODIC.B on the opposite side.

Parameters

<code>in</code>	<code>coef</code>	Value of penalty parameter [Default: 1.e20].
-----------------	-------------------	--

### **void build ( )**

Build the linear system of equations.

Before using this function, one must have properly selected appropriate options for:

- The choice of a steady state or transient analysis. By default, the analysis is stationary
- In the case of transient analysis, the choice of a time integration scheme and a lumped or consistent capacity matrix. If transient analysis is chosen, the lumped capacity matrix option is chosen by default, and the implicit Euler scheme is used by default for time integration.

### **int runOneTimeStep ( )**

Run one time step.

This function performs one time step, once a time integration scheme has been selected.

*Return solution in the case of a scalar equation.*

### 7.83.1 Detailed Description

To solve a system of ordinary differential equations.

The class `ODESolver` enables solving by a numerical scheme a system or ordinary differential equations taking one of the forms:

- A linear system of differential equations of the first-order:  
 $A_1(t)u'(t) + A_0(t)u(t) = f(t)$
- A linear system of differential equations of the second-order:  
 $A_2(t)u''(t) + A_1(t)u'(t) + A_0(t)u(t) = f(t)$
- A system of ordinary differential equations of the form:  
 $u'(t) = f(t, u(t))$

The following time integration schemes can be used:

- Forward Euler scheme (value: `FORWARD_EULER`) for first-order systems
- Backward Euler scheme (value: `BACKWARD_EULER`) for first-order linear systems
- Crank-Nicolson (value: `CRANK_NICOLSON`) for first-order linear systems
- Heun (value: `HEUN`) for first-order systems
- 2nd Order Adams-Bashforth (value: `AB2`) for first-order systems
- 4-th order Runge-Kutta (value: `RK4`) for first-order systems
- 2nd order Backward Differentiation Formula (value: `BDF2`) for linear first-order systems
- Newmark (value: `NEWMARK`) for linear second-order systems with constant matrices

### 7.83.2 Constructor & Destructor Documentation

**ODESolver** ( *TimeScheme* *s*, *real.t time\_step* = *theTimeStep*, *real.t final\_time* = *theFinalTime*, *size.t nb\_eq* = 1 )

Constructor using time discretization data.

Parameters

in	<i>s</i>	Choice of the scheme: To be chosen in the enumerated variable <i>Scheme</i> (see the presentation of the class)
in	<i>time_step</i>	Value of the time step. This value will be modified if an adaptive method is used. The default value for this parameter is the value given by the global variable <code>theTimeStep</code>
in	<i>final_time</i>	Value of the final time (time starts at 0). The default value for this parameter is the value given by the global variable <code>theFinalTime</code>
in	<i>nb_eq</i>	Number of differential equations (size of the system) [Default: 1]

### 7.83.3 Member Function Documentation

**void set ( TimeScheme *s*, real.t *time\_step* = `theTimeStep`, real.t *final\_time* = `theFinalTime` )**

Define data of the differential equation or system.

Parameters

in	<i>s</i>	Choice of the scheme: To be chosen in the enumerated variable <i>Scheme</i> (see the presentation of the class)
in	<i>time_step</i>	Value of the time step. This value will be modified if an adaptive method is used. The default value for this parameter is the value given by the global variable <code>theTimeStep</code>
in	<i>final_time</i>	Value of the final time (time starts at 0). The default value for this parameter is the value given by the global variable <code>theFinalTime</code>

**void setNbEq ( size.t *n* )**

Set the number of equations [Default: 1].

This function is to be used if the default constructor was used

**void setCoef ( real.t *a0*, real.t *a1*, real.t *a2*, real.t *f* )**

Define coefficients in the case of a scalar differential equation.

This function enables giving coefficients of the differential equation as an algebraic expression of time *t* (see the function `fparse`)

Parameters

in	<i>a0</i>	Coefficient of the 0-th order term
in	<i>a1</i>	Coefficient of the 1-st order term
in	<i>a2</i>	Coefficient of the 2-nd order term
in	<i>f</i>	Value of the right-hand side

Note

Naturally, the equation is of the first order if *a2*=0

**void setCoef ( string *a0*, string *a1*, string *a2*, string *f* )**

Define coefficients in the case of a scalar differential equation.

Parameters

in	$a0$	Coefficient of the 0-th order term
in	$a1$	Coefficient of the 1-st order term
in	$a2$	Coefficient of the 2-nd order term
in	$f$	Value of the right-hand side

Note

Naturally, the equation is of the first order if  $a2=0$

**void setLinear ( )**

Claim that ODE is linear.

Claim that the defined ODE (or system of ODEs) is linear

**void setF ( string  $f$  )**

Set time derivative, given as an algebraic expression, for a nonlinear ODE.

This function enables prescribing the value of the 1-st derivative for a 1st order ODE or the 2nd one for a 2nd-order ODE. It is to be used for nonlinear ODEs of the form  $y'(t) = f(t, y(t))$  or  $y''(t) = f(t, y(t), y'(t))$

In the case of a system of ODEs, this function can be called once for each equation, given in the order of the unknowns

Parameters

in	$f$	Expression of the function
----	-----	----------------------------

**void setF ( string  $f$ , int  $i$  )**

Set time derivative, given as an algebraic expression, for a nonlinear ODE.

This function enables prescribing the value of the 1-st derivative for a 1st order ODE or the 2nd one for a 2nd-order ODE. It is to be used for nonlinear ODEs of the form  $y'(t) = f(t, y(t))$  or  $y''(t) = f(t, y(t), y'(t))$

This function is to be used for the  $i$ -th equation of a system of ODEs

Parameters

in	$f$	Expression of the function
in	$i$	Index of equation. Must be not larger than the number of equations

**void setDF ( string  $df$ , int  $i$ , int  $j$  )**

Set time derivative of the function defining the ODE.

This function enables prescribing the value of the 1-st derivative for a 1st order ODE or the 2nd one for a 2nd-order ODE. It is to be used for nonlinear ODEs of the form  $y'(t) = f(t, y(t))$  or  $y''(t) = f(t, y(t), y'(t))$

In the case of a system of ODEs, this function can be called once for each equation, given in the order of the unknowns

**void setdFdt ( string *df*, int *i* )**

Set time derivative of the function defining the ODE.

This function enables prescribing the value of the 1-st derivative for a 1st order ODE or the 2nd one for a 2nd-order ODE. It is to be used for nonlinear ODEs of the form  $y'(t) = f(t, y(t))$  or  $y''(t) = f(t, y(t), y'(t))$

In the case of a system of ODEs, this function can be called once for each equation, given in the order of the unknowns

**void setRK4RHS ( real\_t *f* )**

Set intermediate right-hand side vector for the Runge-Kutta method.

Parameters

in	<i>f</i>	Value of right-hand side
----	----------	--------------------------

**void setRK4RHS ( Vect< real\_t > &*f* )**

Set intermediate right-hand side vector for the Runge-Kutta method.

Parameters

in	<i>f</i>	right-hand side vector
----	----------	------------------------

**void setInitial ( Vect< real\_t > &*u* )**

Set initial condition for a first-order system of differential equations.

Parameters

in	<i>u</i>	Vector containing initial condition for the unknown
----	----------	---

**void setInitial ( real\_t *u*, int *i* )**

Set initial condition for a first-order system of differential equations.

Parameters

in	<i>u</i>	Initial condition for an unknown
in	<i>i</i>	Index of the unknown

**void setInitial ( Vect< real\_t > &*u*, Vect< real\_t > &*v* )**

Set initial condition for a second-order system of differential equations.

Giving the right-hand side at initial time is sometimes required for high order methods like Runge-Kutta

Parameters

in	<i>u</i>	Vector containing initial condition for the unknown
in	<i>v</i>	Vector containing initial condition for the time derivative of the unknown

**void setInitialRHS ( Vect< real,t > &f )**

Set initial RHS for a system of differential equations.

Giving the right-hand side at initial time is sometimes required for high order methods like Runge-Kutta

Parameters

<code>in</code>	<code>f</code>	Vector containing right-hand side at initial time. This vector is helpful for high order methods
-----------------	----------------	--

**void setInitial ( real\_t *u*, real\_t *v* )**

Set initial condition for a second-order ordinary differential equation.

Parameters

<code>in</code>	<code>u</code>	Initial condition (unknown) value
<code>in</code>	<code>v</code>	Initial condition (time derivative of the unknown) value

**void setInitial ( real\_t *u* )**

Set initial condition for a first-order ordinary differential equation.

Parameters

<code>in</code>	<code>u</code>	Initial condition (unknown) value
-----------------	----------------	-----------------------------------

**void setInitialRHS ( real\_t *f* )**

Set initial right-hand side for a single differential equation.

Parameters

<code>in</code>	<code>f</code>	Value of right-hand side at initial time. This value is helpful for high order methods
-----------------	----------------	--

**void setMatrices ( DMatrix< real\_t > & *A0*, DMatrix< real\_t > & *A1* )**

Define matrices for a system of first-order ODEs.

Matrices are given as references to class [DMatrix](#).

Parameters

<code>in</code>	<code>A0</code>	Reference to matrix in front of the 0-th order term (no time derivative)
<code>in</code>	<code>A1</code>	Reference to matrix in front of the 1-st order term (first time derivative)

Remarks

This function has to be called at each time step

**void setMatrices ( DMatrix< real\_t > & *A0*, DMatrix< real\_t > & *A1*, DMatrix< real\_t > & *A2* )**

Define matrices for a system of second-order ODEs.

Matrices are given as references to class [DMatrix](#).

## Parameters

in	$A0$	Reference to matrix in front of the 0-th order term (no time derivative)
in	$A1$	Reference to matrix in front of the 1-st order term (first time derivative)
in	$A2$	Reference to matrix in front of the 2-nd order term (second time derivative)

## Remarks

This function has to be called at each time step

**void seODEVectors ( Vect< real.t > & a0, Vect< real.t > & a1 )**

Define matrices for an implicit nonlinear system of first-order ODEs.

The system has the nonlinear implicit form  $a1(u)' + a0(u) = 0$  Vectors a0, a1 are given as references to class [Vect](#).

## Parameters

in	$a0$	Reference to vector in front of the 0-th order term (no time derivative)
in	$a1$	Reference to vector in front of the 1-st order term (first time derivative)

## Remarks

This function has to be called at each time step

**void seODEVectors ( Vect< real.t > & a0, Vect< real.t > & a1, Vect< real.t > & a2 )**

Define matrices for an implicit nonlinear system of second-order ODEs.

The system has the nonlinear implicit form  $a2(u)'' + a1(u)' + a0(u) = 0$  Vectors a0, a1, a2 are given as references to class [Vect](#).

## Parameters

in	$a0$	Reference to vector in front of the 0-th order term (no time derivative)
in	$a1$	Reference to vector in front of the 1-st order term (first time derivative)
in	$a2$	Reference to vector in front of the 2-nd order term (second time derivative)

## Remarks

This function has to be called at each time step

**void setRHS ( Vect< real.t > & b )**

Set right-hand side vector for a system of ODE.

Parameters

in	<i>b</i>	<a href="#">Vect</a> instance containing right-hand side for a linear system of ordinary differential equations
----	----------	---

**void setRHS ( real.t *f* )**

Set right-hand side for a linear ODE.

Parameters

in	<i>f</i>	Value of the right-hand side for a linear ordinary differential equation
----	----------	--

**void setNewmarkParameters ( real.t *beta*, real.t *gamma* )**

Define parameters for the Newmark scheme.

Parameters

in	<i>beta</i>	Parameter beta [Default: 0.25]
in	<i>gamma</i>	Parameter gamma [Default: 0.5]

**void setConstantMatrix ( )**

Say that matrix problem is constant.

This is useful if the linear system is solved by a factorization method but has no effect otherwise

**void setNonConstantMatrix ( )**

Say that matrix problem is variable.

This is useful if the linear system is solved by a factorization method but has no effect otherwise

**void setLinearSolver ( Iteration *s* = DIRECT\_SOLVER, Preconditioner *p* = DIAG\_PREC )**

Set linear solver data.

Parameters

in	<i>s</i>	Solver identification parameter. To be chosen in the enumeration variable Iteration: DIRECT_SOLVER, CG_SOLVER, CGS_SOLVER, BICG_SOLVER, BICG_STAB_SOLVER, GMRES_SOLVER, QMR_SOLVE← R [Default: DIRECT_SOLVER]
in	<i>p</i>	Preconditioner identification parameter. To be chosen in the enumeration variable Preconditioner: IDENT_PREC, DIAG_PREC, ILU_PREC [Default: DIAG_PREC]

Note

The argument *p* has no effect if the solver is DIRECT\_SOLVER

**void setMaxIter ( int *max.it* )**

Set maximal number of iterations.

This function is useful for a non linear ODE (or system of ODEs) if an implicit scheme is used

Parameters

<b>in</b>	<i>max_it</i>	Maximal number of iterations [Default: 100]
-----------	---------------	---

**void setTolerance ( real\_t toler )**

Set tolerance value for convergence.

This function is useful for a non linear ODE (or system of ODEs) if an implicit scheme is used

Parameters

<b>in</b>	<i>toler</i>	Tolerance value [Default: 1.e-8]
-----------	--------------	----------------------------------

**real\_t runOneTimeStep ( )**

Run one time step.

Returns

Value of new time step if this one is updated

**void run ( bool opt = false )**

Run the time stepping procedure.

Parameters

<b>in</b>	<i>opt</i>	Flag to say if problem matrix is constant while time stepping (true) or not (Default value is false)
-----------	------------	--

Note

This argument is not used if the time stepping scheme is explicit

**real\_t getTimeDerivative ( int i = 1 ) const**

Get time derivative of solution.

Return approximate time derivative of solution in the case of a single equation

Parameters

<b>in</b>	<i>i</i>	Index of component whose time derivative is sought
-----------	----------	--

Returns

Time derivative of the i-th component of the solution

Remarks

If we are solving one equation, this parameter is not used.

**void getTimeDerivative ( Vect< real\_t > & y ) const**

Get time derivative of solution (for a system)

Get approximate time derivative of solution in the case of an ODE system

Parameters

out	y	Vector containing time derivative of solution
-----	---	---

## 7.84 OFELIException Class Reference

To handle exceptions in [OFELI](#).

Inherits `runtime_error`.

### Public Member Functions

- [OFELIException](#) (const std::string &s)  
*This form will be used most often in a throw.*
- [OFELIException](#) ()  
*Throw with no error message.*

### 7.84.1 Detailed Description

To handle exceptions in [OFELI](#).

This class enables using exceptions in programs using [OFELI](#)

### 7.85.2 Member Enumeration Documentation

#### enum `OptMethod`

Choose optimization algorithm.

Enumerator

`GRADIENT` Gradient method

`TRUNCATED_NEWTON` Truncated Newton method

`SIMULATED_ANNEALING` Simulated annealing global optimization method

`NELDER_MEAD` Nelder-Mead global optimization method

`NEWTON` Newton's method

### 7.85.3 Constructor & Destructor Documentation

**OptSolver** ( Vect< real\_t > &  $x$  )

Constructor using vector of optimization variables.

## Parameters

in	$x$	Vector having as size the number of optimization variables. It contains the initial guess for the optimization algorithm.
----	-----	---

## Remarks

After using the member function `run`, the vector  $x$  contains the obtained solution if the optimization procedure was successful

**OptSolver ( MyOpt & *opt*, Vect< real\_t > &  $x$  )**

Constructor using vector of optimization variables.

## Parameters

in	<i>opt</i>	Reference to instance of user defined optimization class. This class inherits from abstract class <a href="#">MyOpt</a> . It must contain the member function <code>double Objective(Vect&lt;double&gt; &amp;x)</code> which returns the value of the objective for a given solution vector $x$ . The user defined class must contain, if the optimization algorithm requires it the member function <code>Gradient(Vect&lt;double&gt; &amp;x, Vect&lt;double&gt; &amp;g)</code> which stores the gradient of the objective in the vector $g$ for a given optimization vector $x$ . The user defined class must also contain, if the optimization algorithm requires it the member function
in	$x$	Vector having as size the number of optimization variables. It contains the initial guess for the optimization algorithm.

## Remarks

After using the member function `run`, the vector  $x$  contains the obtained solution if the optimization procedure was successful

**7.85.4 Member Function Documentation****void setOptMethod ( OptMethod *m* )**

Choose optimization method.

## Parameters

<b>in</b>	<i>m</i>	<p>Enumerated value to choose the optimization algorithm to use. Must be chosen among the enumerated values:</p> <ul style="list-style-type: none"> <li>• GRADIENT: Gradient steepest descent method with projection for bounded constrained problems</li> <li>• TRUNCATED_NEWTON: The Nash's Truncated Newton Algorithm, due to S.G. Nash (Newton-type Minimization via the Lanczos method, SIAM J. Numer. Anal. 21 (1984) 770-778).</li> <li>• SIMULATED_ANNEALING: Global optimization simulated annealing method. See Corana et al.'s article: "← Minimizing Multimodal Functions of Continuous Variables with the Simulated Annealing Algorithm" in the September 1987 (vol. 13, no. 3, pp. 262-280) issue of the ACM Transactions on Mathematical Software.</li> <li>• NELDER_MEAD: Global optimization Nelder-Mead method due to John Nelder, Roger Mead (A simplex method for function minimization, Computer Journal, Volume 7, 1965, pages 308-313). As implemented by R. O'Neill (Algorithm AS 47: Function Minimization Using a Simplex Procedure, Applied Statistics, Volume 20, Number 3, 1971, pages 338-345).</li> </ul>
-----------	----------	--

**void setBC ( const Vect< real\_t > & bc )**

Prescribe boundary conditions as constraints.

This member function is useful in the case of optimization problems where the optimization variable vector is the solution of a partial differential equation. For this case, Dirichlet boundary conditions can be prescribed as constraints for the optimization problem

## Parameters

<b>in</b>	<i>bc</i>	Vector containing the values to impose on degrees of freedom. This vector must have been constructed using the <a href="#">Mesh</a> instance.
-----------	-----------	---

## Remarks

Only degrees of freedom with positive code are taken into account as prescribed

**void setObjective ( string exp )**

Define the objective function to minimize by an algebraic expression.

## Parameters

<b>in</b>	<i>exp</i>	Regular expression defining the objective function
-----------	------------	--

**void setGradient ( string exp, int i = 1 )**

Define a component of the gradient of the objective function to minimize by an algebraic expression.

Parameters

<code>in</code>	<code>exp</code>	Regular expression defining the objective function
<code>in</code>	<code>i</code>	Component of gradient [Default: 1]

**void setHessian ( string *exp*, int *i* = 1, int *j* = 1 )**

Define an entry of the Hessian matrix.

Parameters

<code>in</code>	<code>exp</code>	Regular expression defining the Hessian matrix entry
<code>in</code>	<code>i</code>	<i>i</i> -th row of Hessian matrix [Default: 1]
<code>in</code>	<code>j</code>	<i>j</i> -th column of Hessian matrix [Default: 1]

**void setIneqConstraint ( string *exp*, real *t* *penal* = 1./OFELI\_TOLERANCE )**

Impose an inequality constraint by a penalty method.

The constraint is of the form  $F(x) \leq 0$  where  $F$  is any function of the optimization variable vector  $v$

Parameters

<code>in</code>	<code>exp</code>	Regular expression defining the constraint (the function $F$
<code>in</code>	<code>penal</code>	Penalty parameter (large number) [Default: 1./DBL_EPSILON]

**void setEqConstraint ( string *exp*, real *t* *penal* = 1./OFELI\_TOLERANCE )**

Impose an equality constraint by a penalty method.

The constraint is of the form  $F(x) = 0$  where  $F$  is any function of the optimization variable vector  $v$

Parameters

<code>in</code>	<code>exp</code>	Regular expression defining the constraint (the function $F$
<code>in</code>	<code>penal</code>	Penalty parameter (large number) [Default: 1./DBL_EPSILON]

**void setObjective ( function< real *t*(real *t*)> *f* )**

Define the objective function by a user defined one-variable function.

This function can be used in the case where a user defined function is to be given. To be used in the one-variable case.

Parameters

<code>in</code>	<code>f</code>	Function given as a function of one real variable which is the optimization variable and returning the objective value. This function can be defined by the calling program as a C-function and then cast to an instance of class function
-----------------	----------------	--

**void setObjective ( function< real *t*(Vect< real *t* >)> *f* )**

Define the objective function by a user defined multi-variable function.

This function can be used in the case where a user defined function is to be given. To be used in the multivariable case.

Parameters

<b>in</b>	<i>f</i>	Function given as a function of many real variables and returning the objective value. This function can be defined by the calling program as a C-function and then cast to an instance of class function
-----------	----------	---

**void setGradient ( function< real\_t(real\_t)> f )**

Define the derivative of the objective function by a user defined function.

Parameters

<b>in</b>	<i>f</i>	Function given as a function of a real variable and returning the derivative of the objective value. This function can be defined by the calling program as a C-function and then cast to an instance of class function
-----------	----------	---

**void setGradient ( function< Vect< real\_t >(Vect< real\_t >)> f )**

Define the gradient of the objective function by a user defined function.

Parameters

<b>in</b>	<i>f</i>	Function given as a function of a many real variables and returning the partial derivatives of the objective value. This function can be defined by the calling program as a C-function and then cast to an instance of class function
-----------	----------	--

**void setOptClass ( MyOpt & opt )**

Choose user defined optimization class.

Parameters

<b>in</b>	<i>opt</i>	Reference to inherited user specified optimization class
-----------	------------	--

**void setLowerBound ( size\_t i, real\_t lb )**

Define lower bound for a particular optimization variable.

Method to impose a lower bound for a component of the optimization variable

Parameters

<b>in</b>	<i>i</i>	Index of component to bound (index starts from 1 )
<b>in</b>	<i>lb</i>	Lower bound

**void setUpperBound ( size\_t i, real\_t ub )**

Define upper bound for a particular optimization variable.

Method to impose an upper bound for a component of the optimization variable

Parameters

<b>in</b>	<i>i</i>	Index of component to bound (index starts from 1 )
<b>in</b>	<i>ub</i>	Upper bound

**void setEqBound ( size\_t *i*, real\_t *b* )**

Define value to impose to a particular optimization variable.

Method to impose a value for a component of the optimization variable

Parameters

<b>in</b>	<i>i</i>	Index of component to enforce (index starts from 1 )
<b>in</b>	<i>b</i>	Value to impose

**void setUpperBound ( real\_t *ub* )**

Define upper bound for optimization variable.

Case of a one-variable problem

Parameters

<b>in</b>	<i>ub</i>	Upper bound
-----------	-----------	-------------

**void setUpperBounds ( Vect< real\_t > &*ub* )**

Define upper bounds for optimization variables.

Parameters

<b>in</b>	<i>ub</i>	Vector containing upper values for variables
-----------	-----------	--

**void setLowerBound ( real\_t *lb* )**

Define lower bound for optimization variable.

Case of a one-variable problem

Parameters

<b>in</b>	<i>lb</i>	Lower value
-----------	-----------	-------------

**void setLowerBounds ( Vect< real\_t > &*lb* )**

Define lower bounds for optimization variables.

Parameters

<b>in</b>	<i>lb</i>	Vector containing lower values for variables
-----------	-----------	--

**void setSAOpt ( real\_t *rt*, int *ns*, int *nt*, int &*neps*, int *maxevl*, real\_t *t*, Vect< real\_t > &*vm*, Vect< real\_t > &*xopt*, real\_t &*fopt* )**

Set Simulated annealing options.

Remarks

This member function is useful only if simulated annealing is used.

## Parameters

in	<i>rt</i>	The temperature reduction factor. The value suggested by Corana et al. is .85. See Goffe et al. for more advice.
in	<i>ns</i>	Number of cycles. After <i>ns*nb_var</i> function evaluations, each element of <i>vm</i> is adjusted so that approximately half of all function evaluations are accepted. The suggested value is 20.
in	<i>nt</i>	Number of iterations before temperature reduction. After <i>nt*ns*n</i> function evaluations, temperature (t) is changed by the factor <i>rt</i> . Value suggested by Corana et al. is <i>max(100,5*nb_var)</i> . See Goffe et al. for further advice.
in	<i>neps</i>	Number of final function values used to decide upon termination. See <i>eps</i> . Suggested value is 4
in	<i>maxevl</i>	The maximum number of function evaluations. If it is exceeded, the return <i>code=1</i> .
in	<i>t</i>	The initial temperature. See Goffe et al. for advice.
in	<i>vm</i>	The step length vector. On input it should encompass the region of interest given the starting value <i>x</i> . For point <i>x[i]</i> , the next trial point is selected is from <i>x[i]-vm[i]</i> to <i>x[i]+vm[i]</i> . Since <i>vm</i> is adjusted so that about half of all points are accepted, the input value is not very important (i.e. is the value is off, <i>OptimSA</i> adjusts <i>vm</i> to the correct value).
out	<i>xopt</i>	optimal values of optimization variables
out	<i>fopt</i>	Optimal value of objective

**void setTolerance ( real\_t toler )**

Set error tolerance.

## Parameters

in	<i>toler</i>	Error tolerance for termination. If the final function values from the last <i>neps</i> temperatures differ from the corresponding value at the current temperature by less than <i>eps</i> and the final function value at the current temperature differs from the current optimal function value by less than <i>toler</i> , execution terminates and the value 0 is returned.
----	--------------	---

**real\_t getTemperature ( ) const**

Return the final temperature.

This function is meaningful only if the Simulated Annealing algorithm is used

**int getNbAcc ( ) const**

Return the number of accepted objective function evaluations.

This function is meaningful only if the Simulated Annealing algorithm is used

**int getNbOutOfBounds ( ) const**

Return the total number of trial function evaluations that would have been out of bounds.

This function is meaningful only if the Simulated Annealing algorithm is used

**int run ( )**

Run the optimization algorithm.

This function runs the optimization procedure using default values for parameters. To modify these values, use the function run with arguments

**int run ( real.t toler, int max.it )**

Run the optimization algorithm.

Parameters

in	toler	Tolerance value for convergence testing
in	max.it	Maximal number of iterations to achieve convergence

**real.t getSolution ( ) const**

Return solution in the case of a one variable optimization.

In the case of a one variable problem, the solution value is returned, if the optimization procedure was successful

**void getSolution ( Vect< real.t > &x ) const**

Get solution vector.

The vector  $x$  contains the solution of the optimization problem. Note that if the constructor using an initial vector was used, the vector will contain the solution once the member function run has been used (If the optimization procedure was successful)

Parameters

out	$x$	solution vector
-----	-----	-----------------

## 7.86 Partition Class Reference

To partition a finite element mesh into balanced submeshes.

### Public Member Functions

### 7.86.1 Detailed Description

To partition a finite element mesh into balanced submeshes.

Class [Partition](#) enables partitioning a given mesh into a given number of submeshes with a minimal connectivity. [Partition](#) uses the well known `metis` library that is included in the [OFELI](#) library. A more detailed description of `metis` can be found in the web site:

[http://www.csit.fsu.edu/~burkardt/c\\_src/metis/metis.html](http://www.csit.fsu.edu/~burkardt/c_src/metis/metis.html)

### 7.86.2 Constructor & Destructor Documentation

**Partition** ( Mesh & *mesh*, size\_t *n* )

Constructor to partition a mesh into submeshes.

Parameters

<b>in</b>	<i>mesh</i>	<a href="#">Mesh</a> instance
<b>in</b>	<i>n</i>	Number of submeshes

**Partition ( Mesh & *mesh*, int *n*, vector< int > & *epart* )**

Constructor using already created submeshes.

Parameters

<b>in</b>	<i>mesh</i>	<a href="#">Mesh</a> instance
<b>in</b>	<i>n</i>	Number of submeshes
<b>in</b>	<i>epart</i>	Vector containing for each element its submesh label (Running from 0 to n-1)

### 7.86.3 Member Function Documentation

**size\_t getNodeLabelInSubMesh ( size\_t *sm*, size\_t *label* ) const**

Return node label in subdomain by giving its label in initial mesh.

Parameters

<b>in</b>	<i>sm</i>	Label of submesh
<b>in</b>	<i>label</i>	Label of node in initial mesh

**size\_t getNodeLabelInMesh ( size\_t *sm*, size\_t *label* ) const**

Return node label in initial mesh by giving its label in submesh.

Parameters

<b>in</b>	<i>sm</i>	Label of submesh
<b>in</b>	<i>label</i>	<a href="#">Node</a> label

**size\_t getSubMesh ( size\_t *sm*, size\_t *i* ) const**

Return index of submesh that contains the i-th side label in sub-mesh *sm*

Parameters

<b>in</b>	<i>sm</i>	Submesh index
<b>in</b>	<i>i</i>	<a href="#">Side</a> label

Returns

Index of submesh

**Mesh& getSubMesh ( size\_t *i* ) const**

Return reference to submesh.

Parameters

<b>in</b>	<i>i</i>	Submesh index
-----------	----------	---------------

Returns

Reference to corresponding [Mesh](#) instance

**size\_t getFirstSideLabel ( size\_t *sm*, size\_t *i* ) const**

Return i-th side label in a given submesh.

Parameters

<b>in</b>	<i>sm</i>	Index of submesh
<b>in</b>	<i>i</i>	Label of side

**size\_t getSecondSideLabel ( size\_t *sm*, size\_t *i* ) const**

Return side label in the neighbouring submesh corresponding to i-th side label in sub-mesh *sm*

Parameters

<b>in</b>	<i>sm</i>	Label of submesh
<b>in</b>	<i>i</i>	<a href="#">Side</a> label

**int getNbConnectInSubMesh ( int *n*, int *s* ) const**

Get number of connected nodes in a submesh.

Parameters

<b>in</b>	<i>n</i>	Label of node for which connections are counted
<b>in</b>	<i>s</i>	Label of submesh (starting from 0)

**int getNbConnectOutSubMesh ( int *n*, int *s* ) const**

Get number of connected nodes out of a submesh.

Parameters

<b>in</b>	<i>n</i>	Label of node for which connections are counted
<b>in</b>	<i>s</i>	Label of submesh (starting from 0)

**void put ( size\_t *n*, string *file* ) const**

Save a submesh in file.

Parameters

<b>in</b>	<i>n</i>	Label of submesh
<b>in</b>	<i>file</i>	Name of file in which submesh is saved

## 7.87 Penta6 Class Reference

Defines a 6-node pentahedral finite element using  $P_1$  interpolation in local coordinates (*s.x*, *s.y*) and  $Q_1$  isoparametric interpolation in local coordinates (*s.x*, *s.z*) and (*s.y*, *s.z*).

Inheritance diagram for Penta6:

- [real.t](#) [getMaxEdgeLength](#) () const  
*Return Maximum length of pentahedron edges.*
- [real.t](#) [getMinEdgeLength](#) () const  
*Return Mimimum length of pentahedron edges.*

### 7.87.1 Detailed Description

Defines a 6-node pentahedral finite element using  $P_1$  interpolation in local coordinates  $(s.x, s.y)$  and  $Q_1$  isoparametric interpolation in local coordinates  $(s.x, s.z)$  and  $(s.y, s.z)$ .

The reference element is the cartesian product of the standard reference triangle with the line  $[-1, 1]$ . The nodes are ordered as follows: **Node 1** in reference element is at  $s=(1,0,0)$  **Node 2** in reference element is at  $s=(0,1,0)$  **Node 3** in reference element is at  $s=(0,0,0)$  **Node 4** in reference element is at  $s=(1,0,1)$  **Node 5** in reference element is at  $s=(0,1,1)$  **Node 6** in reference element is at  $s=(0,0,1)$

The user must take care to the fact that determinant of jacobian and other quantities depend on the point in the reference element where they are calculated. For this, before any utilization of shape functions or jacobian, function `setLocal()` must be invoked.

### 7.87.2 Constructor & Destructor Documentation

**Penta6 ( const Element \* element )**

Constructor when data of [Element](#) e1 are given.

Parameters

in	<i>element</i>	Pointer to <a href="#">Element</a>
----	----------------	------------------------------------

### 7.87.3 Member Function Documentation

**void setLocal ( const Point< real.t > & s )**

Initialize local point coordinates in element.

Parameters

in	<i>s</i>	<a href="#">Point</a> in the reference element This function computes jacobian, shape functions and their partial derivatives at <i>s</i> . Other member functions only return these values.
----	----------	--

**vector<Point<real.t> > DSh ( ) const**

Return partial derivatives of shape functions of element nodes.

Returns

[LocalVect](#) instance of partial derivatives of shape functions *e.g.* `dsh(i).x`, `dsh(i).y`, are partial derivatives of the *i*-th shape function.

Note

The local point at which the derivatives are computed must be chosen before by using the member function `setLocal`

## 7.88 PhaseChange Class Reference

This class enables defining phase change laws for a given material.

### Public Member Functions

- virtual `~PhaseChange()`  
*Destructor.*
- int `E2T(real_t &H, real_t &T, real_t &gamma)`  
*Calculate temperature from enthalpy.*
- virtual int `EnthalpyToTemperature(real_t &H, real_t &T, real_t &gamma)`  
*Virtual function to calculate temperature from enthalpy.*
- void `setMaterial(Material &m, int code)`  
*Choose Material instance and material code.*
- `Material &getMaterial()` const  
*Return reference to Material instance.*

### 7.88.1 Detailed Description

This class enables defining phase change laws for a given material.

These laws are predefined for a certain number of materials. The user can set himself a specific behavior for his own materials by defining a class that inherits from `PhaseChange`. The derived class must have at least the member function

int `EnthalpyToTemperature(real_t &H, real_t &T, real_t &gamma)`

### 7.88.2 Member Function Documentation

int `E2T( real_t & H, real_t & T, real_t & gamma )`

Calculate temperature from enthalpy.

This member function is to be called in any equation class that needs phase change laws.

Parameters

in	$H$	Enthalpy value
out	$T$	Calculated temperature value
out	$gamma$	Maximal slope of the curve $H \rightarrow T$

virtual int `EnthalpyToTemperature( real_t & H, real_t & T, real_t & gamma )` [virtual]

Virtual function to calculate temperature from enthalpy.

This member function must be implemented in any derived class in order to define user's own material laws.

Parameters

in	$H$	Enthalpy value
out	$T$	Calculated temperature value
out	$gamma$	Maximal slope of the curve $H \rightarrow T$

- `T_ z`  
*Third coordinate.*

### 7.89.1 Detailed Description

**template<class T\_>class OFELI::Point< T\_ >**

Defines a point with arbitrary type coordinates.

Operators = and () are overloaded.

Template Parameters

<code>T_</code>	Data type (double, float, complex<double>, ...)
-----------------	---

Author

Rachid Touzani

Copyright

GNU Lesser Public License

### 7.89.2 Constructor & Destructor Documentation

**Point ( T\_ a, T\_ b = T\_ (0), T\_ c = T\_ (0) )**

Constructor that assigns a, b to x-, y- and z-coordinates respectively.

Default values for b and c are 0

### 7.89.3 Member Function Documentation

**T\_& operator() ( size\_t i )**

Operator (): Non constant version.

Values i = 1, 2, 3 correspond to x, y and z respectively

**const T\_& operator() ( size\_t i ) const**

Operator (): Constant version.

Values i = 1, 2, 3 correspond to x, y and z respectively

**T\_& operator[] ( size\_t i )**

Operator []: Non constant version.

Values i = 0, 1, 2 correspond to x, y and z respectively

**const T\_& operator[] ( size\_t i ) const**

Operator []: Constant version.

Values i = 0, 1, 2 correspond to x, y and z respectively

**Point<T\_>& operator+= ( const Point< T\_ > & p )**

Operator +=

Add point p to current instance

**Point<T\_>& operator-= ( const Point< T\_ > & p )**

Operator -=

Subtract point p from current instance

**Point<T\_>& operator= ( const T\_ & a )**

Operator =

Assign constant a to current instance coordinates

**Point<T\_>& operator+= ( const T\_ & a )**

Operator +=

Add constant a to current instance coordinates

**Point<T\_>& operator-= ( const T\_ & a )**

Operator -=

Subtract constant a from current instance coordinates

**Point<T\_>& operator\*= ( const T\_ & a )**

Operator \*=

Multiply constant a by current instance coordinates

**Point<T\_>& operator/= ( const T\_ & a )**

Operator /=

Divide current instance coordinates by a

**bool operator== ( const Point< T\_ > & p )**

Operator ==

Return true if current instance is equal to p, false otherwise.

**bool operator!= ( const Point< T\_ > & p )**

Operator !=

Return false if current instance is equal to p, true otherwise.

**void Normalize ( )**

Normalize vector.

Divide vector components by its 2-norm

**bool isCloseTo ( const Point< real\_t > & a, real\_t toler = OFELI\_TOLERANCE ) const**

Return true if current point is close to instance a (up to tolerance toler)

Default value for toler is the OFELI\_TOLERANCE constant.

**T\_ operator, ( const Point< T\_ > & p ) const**

Return Dot (scalar) product of two vectors.

A typical use of this operator is double a = (p,q) where p and q are 2 instances of Point<double>

Parameters

in	p	Point instance by which the current instance is multiplied
----	---	--

## 7.90 Point2D< T\_ > Class Template Reference

Defines a 2-D point with arbitrary type coordinates.

### 7.90.2 Constructor & Destructor Documentation

`Point2D` ( `T_ a`, `T_ b` = `T_ (0)` )

Constructor that assigns a, b to x-, y- and y-coordinates respectively.

Default value for b is 0

### 7.90.3 Member Function Documentation

`T_& operator()` ( `size_t i` )

`Operator()` : Non constant version.

Values i = 1, 2 correspond to x and y respectively

**const T\_& operator() ( size\_t i ) const**

Operator() : Constant version.

Values i=1,2 correspond to x and y respectively

**T\_& operator[] ( size\_t i )**

Operator[]: Non constant version.

Values i=0,1 correspond to x and y respectively

**const T\_& operator[] ( size\_t i ) const**

Operator[] Constant version.

Values i=0,1 correspond to x and y respectively

**Point2D<T\_>& operator= ( const Point2D< T\_ > & p )**

Operator =

Assign point p to current instance

**Point2D<T\_>& operator+= ( const Point2D< T\_ > & p )**

Operator +=

Add point p to current instance

**Point2D<T\_>& operator-= ( const Point2D< T\_ > & p )**

Operator -=

Subtract point p from current instance

**Point2D<T\_>& operator= ( const T\_ & a )**

Operator =

Assign constant a to current instance coordinates

**Point2D<T\_>& operator+= ( const T\_ & a )**

Operator +=

Add constant a to current instance coordinates

**Point2D<T\_>& operator-= ( const T\_ & a )**

Operator -=

Subtract constant a from current instance coordinates

**Point2D<T\_>& operator\*= ( const T\_ & a )**

Operator \*=

Multiply constant a by current instance coordinates

**Point2D<T\_>& operator/= ( const T\_ & a )**

Operator /=

Divide current instance coordinates by a

```
bool operator==( const Point2D< T_ > & p )
```

Operator ==

Return true if current instance is equal to p, false otherwise.

```
bool operator!=( const Point2D< T_ > & p )
```

Operator !=

Return false if current instance is equal to p, true otherwise.

## 7.91 Polygon Class Reference

To store and treat a polygonal figure.

### 7.91.1 Detailed Description

To store and treat a polygonal figure.

### 7.91.2 Constructor & Destructor Documentation

**Polygon ( const Vect< Point< real\_t > > &v, int code = 1 )**

Constructor.

Parameters

in	<i>v</i>	Vect instance containing list of coordinates of polygon vertices
in	<i>code</i>	Code to assign to the generated domain (Default value = 1)

### 7.91.3 Member Function Documentation

**void setVertices ( const Vect< Point< real\_t > > &v )**

Assign vertices of polygon.

Parameters

in	<i>v</i>	Vector containing vertices coordinates in counter clockwise order
----	----------	---

**real\_t getSignedDistance ( const Point< real\_t > &p ) const** [virtual]

Return signed distance of a given point from the current polygon.

The computed distance is negative if p lies in the polygon, negative if it is outside, and 0 on its boundary

Parameters

in	<i>p</i>	Point<double> instance
----	----------	------------------------

Reimplemented from [Figure](#).

**Polygon& operator+= ( Point< real\_t > a )**

Operator +=.

Translate polygon by a vector a

**Polygon& operator+= ( real\_t a )**

Operator \*+=.

Scale polygon by a factor a

## 7.92 `Prec< T_ >` Class Template Reference

### 7.92.1 Detailed Description

**template<class T\_>class OFELI::Prec< T\_ >**

To set a preconditioner.

The preconditioner type is chosen in the constructor

Template Parameters

<code>&lt;T_&gt;</code>	Data type (real_t, float, complex<real_t>, ...)
-------------------------	---

Author

Rachid Touzani

Copyright

GNU Lesser Public License

### 7.92.2 Constructor & Destructor Documentation

Prec ( int *type* )

Constructor that chooses preconditioner.

Parameters

<code>in</code>	<i>type</i>	Preconditioner type: <ul style="list-style-type: none"> <li>• <code>IDENT_PREC</code>: Identity preconditioner (No preconditioning)</li> <li>• <code>DIAG_PREC</code>: Diagonal preconditioner</li> <li>• <code>DILU_PREC</code>: Diagonal Incomplete factorization preconditioner</li> <li>• <code>ILU_PREC</code>: Incomplete factorization preconditioner</li> <li>• <code>SSOR_PREC</code>: SSOR (Symmetric Successive Over Relaxation) preconditioner</li> </ul>
-----------------	-------------	---

**`Prec ( const SpMatrix< T_ > & A, int type = DIAG_PREC )`**

Constructor using matrix of the linear system to precondition.

Parameters

<code>in</code>	<i>A</i>	Matrix to precondition
<code>in</code>	<i>type</i>	Preconditioner type: <ul style="list-style-type: none"> <li>• <code>IDENT_PREC</code>: Identity preconditioner (No preconditioning)</li> <li>• <code>DIAG_PREC</code>: Diagonal preconditioner</li> <li>• <code>DILU_PREC</code>: Diagonal Incomplete factorization preconditioner</li> <li>• <code>ILU_PREC</code>: Incomplete factorization preconditioner</li> <li>• <code>SSOR_PREC</code>: SSOR (Symmetric Successive Over Relaxation) preconditioner</li> </ul>

**`Prec ( const Matrix< T_ > * A, int type = DIAG_PREC )`**

Constructor using matrix of the linear system to precondition.

Parameters

<code>in</code>	<i>A</i>	Pointer to abstract <a href="#">Matrix</a> class to precondition
<code>in</code>	<i>type</i>	Preconditioner type: <ul style="list-style-type: none"> <li>• <code>IDENT_PREC</code>: Identity preconditioner (No preconditioning)</li> <li>• <code>DIAG_PREC</code>: Diagonal preconditioner</li> <li>• <code>DILU_PREC</code>: Diagonal Incomplete factorization preconditioner</li> <li>• <code>ILU_PREC</code>: Incomplete factorization preconditioner</li> <li>• <code>SSOR_PREC</code>: SSOR (Symmetric Successive Over Relaxation) preconditioner</li> </ul>

### 7.92.3 Member Function Documentation

**void setType ( int *type* )**

Define preconditioner type.

Parameters

<b>in</b>	<i>type</i>	Preconditioner type: <ul style="list-style-type: none"> <li>• IDENT_PREC: Identity preconditioner (No preconditioning)</li> <li>• DIAG_PREC: Diagonal preconditioner</li> <li>• DILU_PREC: Diagonal Incomplete factorization preconditioner</li> <li>• ILU_PREC: Incomplete factorization preconditioner</li> <li>• SSOR_PREC: SSOR (Symmetric Successive Over Relaxation) preconditioner</li> </ul>
-----------	-------------	--

**void setMatrix ( const Matrix<  $T_$  > \* A )**

Define pointer to matrix for preconditioning (if this one is abstract)

Parameters

<b>in</b>	<i>A</i>	Matrix to precondition
-----------	----------	------------------------

**void setMatrix ( const SpMatrix<  $T_$  > & A )**

Define the matrix for preconditioning.

Parameters

<b>in</b>	<i>A</i>	Matrix to precondition (instance of class <a href="#">SpMatrix</a> )
-----------	----------	--

**void solve ( Vect<  $T_$  > & x ) const**

Solve a linear system with preconditioning matrix.

Parameters

<b>in,out</b>	<i>x</i>	Right-hand side on input and solution on output.
---------------	----------	--

**void solve ( const Vect<  $T_$  > & b, Vect<  $T_$  > & x ) const**

Solve a linear system with preconditioning matrix.

Parameters

<b>in</b>	<i>b</i>	Right-hand side
<b>out</b>	<i>x</i>	Solution vector

**void TransSolve ( Vect<  $T_$  > & x ) const**

Solve a linear system with transposed preconditioning matrix.

Parameters

in,out	$x$	Right-hand side in input and solution in output.
--------	-----	--

**void TransSolve ( const Vect< T\_ > & b, Vect< T\_ > & x ) const**

Solve a linear system with transposed preconditioning matrix.

Parameters

in	$b$	Right-hand side vector
out	$x$	Solution vector

## 7.93 Prescription Class Reference

To prescribe various types of data by an algebraic expression. Data may consist in boundary conditions, forces, tractions, fluxes, initial condition. All these data types can be defined through an enumerated variable.

### Public Member Functions

### 7.93.1 Detailed Description

To prescribe various types of data by an algebraic expression. Data may consist in boundary conditions, forces, tractions, fluxes, initial condition. All these data types can be defined through an enumerated variable.

Author

Rachid Touzani

Copyright

GNU Lesser Public License

### 7.93.2 Constructor & Destructor Documentation

**Prescription ( Mesh & mesh, const std::string & file )**

Constructor that gives an instance of class [Mesh](#) and the data file name.

It reads parameters in [Prescription](#) Format from this file.

Parameters

<code>in</code>	<i>mesh</i>	<a href="#">Mesh</a> instance
<code>in</code>	<i>file</i>	Name of <a href="#">Prescription</a> file

### 7.93.3 Member Function Documentation

**int get ( EqDataType *type*, Vect< real.t > & *v*, real.t *time* = 0, size.t *dof* = 0 )**

Read data in the given file and stores in a [Vect](#) instance for a chosen DOF. The input value type determines the type of data to read.

Parameters

<code>in</code>	<i>type</i>	<p>Type of data to seek. To choose among the enumerated values:</p> <ul style="list-style-type: none"> <li>• BOUNDARY_CONDITION: Read values for (Dirichlet) boundary conditions</li> <li>• BOUNDARY_FORCE: Read values for boundary force (Neumann boundary condition). The values TRACTION and FLUX have the same effect.</li> <li>• BODY_FORCE: Read values for body (or volume) forces. The value SOURCE has the same effect.</li> <li>• POINT_FORCE: Read values for pointwise forces</li> <li>• CONTACT_DISTANCE: Read values for contact distance (for contact mechanics)</li> <li>• INITIAL_FIELD: Read values for initial solution</li> <li>• SOLUTION: Read values for a solution vector</li> </ul>
-----------------	-------------	---

in,out	<i>v</i>	<a href="#">Vect</a> instance that is instantiated on input and filled on output
in	<i>time</i>	Value of time for which data is read [Default: 0].
in	<i>dof</i>	DOF to store (Default is 0: All DOFs are chosen).

### 7.94 Quad4 Class Reference

Defines a 4-node quadrilateral finite element using  $Q_1$  isoparametric interpolation.

Inheritance diagram for Quad4:

*Return maximal edge length of quadrilateral.*
- **real.t** **getMinEdgeLength** () const  
*Return minimal edge length of quadrilateral.*

### 7.94.1 Detailed Description

Defines a 4-node quadrilateral finite element using  $Q_1$  isoparametric interpolation.

The reference element is the square  $[-1, 1] \times [-1, 1]$ . The user must take care to the fact that determinant of jacobian and other quantities depend on the point in the reference element where they are calculated. For this, before any utilization of shape functions or jacobian, function **setLocal()** must be invoked.

Author

Rachid Touzani

Copyright

GNU Lesser Public License

### 7.94.2 Constructor & Destructor Documentation

**Quad4** ( const **Element** \* *element* )

Constructor when data of **Element** e1 are given.

Parameters

in	<i>element</i>	Pointer to <b>Element</b>
----	----------------	---------------------------

**Quad4** ( const **Side** \* *side* )

Constructor when data of **Side** sd are given.

Parameters

in	<i>side</i>	Pointer to <b>Side</b>
----	-------------	------------------------

### 7.94.3 Member Function Documentation

**void setLocal** ( const **Point**< **real.t** > & s )

Initialize local point coordinates in element.

Parameters

in	s	<a href="#">Point</a> in the reference element This function computes jacobian, shape functions and their partial derivatives at s. Other member functions only return these values.
----	---	--

```
void atGauss ( int n, std::vector< real_t > & sh, std::vector< Point< real_t > > & dsh,
std::vector< real_t > & w )
```

Calculate shape functions and their partial derivatives and integration weights.

Parameters

in	n	Number of Gauss-Legendre integration points in each direction
in	sh	Vector of shape functions at <a href="#">Gauss</a> points
in	dsh	Vector of shape function derivatives at <a href="#">Gauss</a> points
in	w	Weights of integration formula at <a href="#">Gauss</a> points

```
Point<real_t> Grad ( const LocalVect< real_t, 4 > & u, const Point< real_t > & s )
```

Return gradient of a function defined at element nodes.

Parameters

in	u	Vector of values at nodes
in	s	Local coordinates (in $[-1, 1] * [-1, 1]$ ) of point where the gradient is evaluated

Returns

Value of gradient

Note

If the derivatives of shape functions were not computed before calling this function (by calling `setLocal`), this function will compute them

## 7.95 Reconstruction Class Reference

To perform various reconstruction operations.

### 7.95.1 Detailed Description

To perform various reconstruction operations.

This class enables various reconstruction operations like smoothing, projections, ...

Author

Rachid Touzani

Copyright

GNU Lesser Public License

### 7.95.2 Member Function Documentation

**void P0toP1 ( const Vect< real\_t > & *u*, Vect< real\_t > & *v* )**

Smooth an elementwise field to obtain a nodewise field by  $L^2$  projection.

Parameters

in	<i>u</i>	Vect instance that contains field to smooth
out	<i>v</i>	Vect instance that contains on output smoothed field

**void DP1toP1 ( const Vect< real\_t > & *u*, Vect< real\_t > & *v* )**

Smooth an Discontinuous P1 field to obtain a nodewise (Continuous P<sub>1</sub>) field by  $L^2$  projection.

Parameters

in	<i>u</i>	Vect instance that contains field to smooth
out	<i>v</i>	Vect instance that contains on output smoothed field

Warning

This function is valid for P<sub>1</sub> triangles (2-D) only.

## 7.96 Rectangle Class Reference

To store and treat a rectangular figure.

Inheritance diagram for Rectangle:

### 7.96.1 Detailed Description

To store and treat a rectangular figure.

### 7.96.2 Constructor & Destructor Documentation

**Rectangle** ( const [Point](#)< [real.t](#) > & *bbm*, const [Point](#)< [real.t](#) > & *bbM*, int *code* = 1 )

Constructor.  
Parameters

---

in	<i>bbm</i>	Left Bottom point of rectangle
in	<i>bbM</i>	Right Top point of rectangle
in	<i>code</i>	Code to assign to rectangle

### 7.96.3 Member Function Documentation

**void setBoundingBox ( const Point< real\_t > & *bbm*, const Point< real\_t > & *bbM* )**

Assign bounding box of the rectangle.

Parameters

in	<i>bbm</i>	Left Bottom point
in	<i>bbM</i>	Right Top point

**real\_t getSignedDistance ( const Point< real\_t > & *p* ) const** [virtual]

Return signed distance of a given point from the current rectangle.

The computed distance is negative if *p* lies in the rectangle, negative if it is outside, and 0 on its boundary

Parameters

in	<i>p</i>	Point<double> instance
----	----------	------------------------

Reimplemented from [Figure](#).

**Rectangle& operator+=( Point< real\_t > *a* )**

Operator +=.

Translate rectangle by a vector *a*

**Rectangle& operator+=( real\_t *a* )**

Operator \*+=.

Scale rectangle by a factor *a*

## 7.97 Side Class Reference

To store and treat finite element sides (edges in 2-D or faces in 3-D)

### Public Types

- enum [SideType](#) {  
[INTERNAL\\_SIDE](#) = 0,  
[EXTERNAL\\_BOUNDARY](#) = 1,  
[INTERNAL\\_BOUNDARY](#) = 2 }

### Public Member Functions

- [Side](#) ()  
*Default Constructor.*
- [Side](#) (size\_t label, const string &shape)  
*Constructor initializing side label and shape.*
- [Side](#) (size\_t label, int shape)

- Constructor initializing side label and shape.

  - `Side (const Side &sd)`

Copy constructor.
- `~Side ()`

Destructor.
- `void Add (Node *node)`

Insert a node at end of list of nodes of side.
- `void Add (Edge *edge)`

Insert an edge at end of list of edges of side.
- `void setLabel (size_t i)`

Define label of side.
- `void setFirstDOF (size_t n)`

Define First DOF.
- `void setNbDOF (size_t nb_dof)`

Set number of degrees of freedom (DOF).
- `void DOF (size_t i, size_t dof)`

Define label of DOF.
- `void setDOF (size_t &first_dof, size_t nb_dof)`

Define number of DOF.
- `void setCode (size_t dof, int code)`

Assign code to a DOF.
- `void Replace (size_t label, Node *node)`

Replace a node at a given local label.
- `void Add (Element *el)`

Set pointer to neighbor element.
- `void set (Element *el, size_t i)`

Set pointer to neighbor element.
- `void setNode (size_t i, Node *node)`

Assign a node given by its pointer as the *i*-th node of side.
- `void setOnBoundary ()`

Say that the side is on the boundary.
- `int getShape () const`

Return side's shape.
- `size_t getLabel () const`

Return label of side.
- `size_t n () const`

Return label of side.
- `size_t getNbNodes () const`

Return number of side nodes.
- `size_t getNbVertices () const`

Return number of side vertices.
- `size_t getNbEq () const`

Return number of side equations.
- `size_t getNbDOF () const`

Return number of DOF.
- `int getCode (size_t dof=1) const`

- Return code for a given DOF of node.*

  - `size_t getDOF (size_t i) const`

*Return label of  $i$ -th dof.*
- `size_t getFirstDOF () const`

*Return label of first dof of node.*
- `Node * getPtrNode (size_t i) const`

*Return pointer to node of local label  $i$ .*
- `Node * operator() (size_t i) const`

*Operator ().*
- `size_t getNodeLabel (size_t i) const`

*Return global label of node with given local label.*
- `Element * getNeighborElement (size_t i) const`

*Return pointer to  $i$ -th side neighboring element.*
- `Element * getOtherNeighborElement (Element *el) const`

*Return pointer to other neighboring element than given one.*
- `Point< real_t > getNormal () const`

*Return normal vector to side.*
- `Point< real_t > getUnitNormal () const`

*Return unit normal vector to side.*
- `int isOnBoundary () const`

*Boundary side or not.*
- `int isReferenced ()`

*Say if side has a nonzero code or not.*
- `real_t getMeasure () const`

*Return measure of side.*
- `Point< real_t > getCenter () const`

*Return coordinates of center of side.*
- `size_t Contains (const Node *nd) const`

*Say if a given node belongs to current side.*
- `void setActive (bool opt=true)`

*Set side is active (default) or not if argument is `false`*
- `bool isActive () const`

*Return `true` or `false` whether side is active or not.*
- `int getLevel () const`

*Return side level Side level increases when side is refined (starting from 0). If the level is 0, then the element has no father.*
- `void setChild (Side *sd)`

*Assign side as child of current one and assign current side as father.*
- `Side * getParent () const`

*Return pointer to parent side Return null if no parent.*
- `Side * getChild (size_t i) const`

*Return pointer to  $i$ -th child side Returns null pointer is no childs.*
- `size_t getNbChilds () const`

*Return number of children of side.*

### 7.97.1 Detailed Description

To store and treat finite element sides (edges in 2-D or faces in 3-D)

Defines a side of a finite element mesh. The sides are given in particular by their shapes and a list of nodes. Each node can be accessed by the member function [getPtrNode\(\)](#). The string defining the element shape must be chosen according to the following list:

Shape Shape name Dimension Min. number of nodes Line line 3 2 [Triangle](#) tria 3 3 Quadrilateral quad 3 4

Author

Rachid Touzani

Copyright

GNU Lesser Public License

### 7.97.2 Member Enumeration Documentation

**enum SideType**

To select side type (boundary side or not).

Enumerator

*INTERNAL\_SIDE* Internal side

*EXTERNAL\_BOUNDARY* [Side](#) on external boundary

*INTERNAL\_BOUNDARY* [Side](#) on internal boundary

### 7.97.3 Constructor & Destructor Documentation

**Side ( *size\_t label*, *const string & shape* )**

Constructor initializing side label and shape.

Parameters

<i>in</i>	<i>label</i>	Label to assign to side.
<i>in</i>	<i>shape</i>	Shape of side (See class description).

**Side ( *size\_t label*, *int shape* )**

Constructor initializing side label and shape.

Parameters

<i>in</i>	<i>label</i>	to assign to side.
<i>in</i>	<i>shape</i>	of side (See enum ElementShape in <a href="#">Mesh</a> ).

### 7.97.4 Member Function Documentation

**void DOF ( *size\_t i*, *size\_t dof* )**

Define label of DOF.

Parameters

<code>in</code>	<code>i</code>	DOF index
<code>in</code>	<code>dof</code>	Its label

**void setDOF ( size\_t & *first\_dof*, size\_t *nb\_dof* )**

Define number of DOF.

Parameters

<code>in,out</code>	<code>first_dof</code>	Label of the first DOF in input that is actualized
<code>in</code>	<code>nb_dof</code>	Number of DOF

**void setCode ( size\_t *dof*, int *code* )**

Assign code to a DOF.

Parameters

<code>in</code>	<code>dof</code>	DOF to which code is assigned
<code>in</code>	<code>code</code>	Code to assign

**void Add ( Element \* *el* )**

Set pointer to neighbor element.

Parameters

<code>in</code>	<code>el</code>	Pointer to element to add as a neighbor element
-----------------	-----------------	---

Remarks

This function adds the pointer *el* only if this one is not a null pointer

**void set ( Element \* *el*, size\_t *i* )**

Set pointer to neighbor element.

Parameters

<code>in</code>	<code>el</code>	Pointer to element to set as a neighbor element
<code>in</code>	<code>i</code>	Local number of neighbor element

Remarks

This function differs from the Add by the fact that the local label of neighbor element is given

**int getCode ( size\_t *dof* = 1 ) const**

Return code for a given DOF of node.

Parameters

<b>in</b>	<i>dof</i>	Local label of degree of freedom. [Default: 1]
-----------	------------	--

**Node\* operator() ( size\_t i ) const**

Operator ().

Return pointer to node of local label i.

**Element\* getNeighborElement ( size\_t i ) const**

Return pointer to i-th side neighboring element.

Parameters

<b>in</b>	<i>i</i>	Local label of neighbor element (must be equal to 1 or 2).
-----------	----------	--

**Element\* getOtherNeighborElement ( Element \* el ) const**

Return pointer to other neighboring element than given one.

Parameters

<b>in</b>	<i>el</i>	Pointer to a given neighbor element
-----------	-----------	-------------------------------------

Remarks

If the side is on the boundary this function returns null pointer

**Point<real\_t> getNormal ( ) const**

Return normal vector to side.

The normal vector is oriented from the first neighbor element to the second one.

Warning

The norm of this vector is equal to the measure of the side (length of the edge in 2-D and area of the face in 3-D), and To get the unit normal, use rather the member function `getUnitNormal`.

**Point<real\_t> getUnitNormal ( ) const**

Return unit normal vector to side.

The unit normal vector is oriented from the first neighbor element to the second one.

Remarks

The norm of this vector is equal to one.

**int isOnBoundary ( ) const**

Boundary side or not.

Returns 1 or -1 if side is on boundary Depending on whether the first or the second neighbor element is defined Returns 0 if side is an inner one

Remarks

This member function is valid only if member function `Mesh::getAllSides()` or `Mesh::getBoundarySides()` has been called before.

**real\_t getMeasure ( ) const**

Return measure of side.

This member function returns length or area of side. In case of quadrilaterals it returns determinant of Jacobian of mapping between reference and actual side

**size\_t Contains ( const Node \* nd ) const**

Say if a given node belongs to current side.

Parameters

in	nd	Pointer to searched node
----	----	--------------------------

Returns

index (local label) of node if found, 0 if not

**void setChild ( Side \* sd )**

Assign side as child of current one and assign current side as father.

This function is principally used when refining is invoked (*e.g.* for mesh adaption)

Parameters

in	sd	Pointer to side to assign
----	----	---------------------------

## 7.98 SideList Class Reference

Class to construct a list of sides having some common properties.

### Public Member Functions

- [SideList](#) ([Mesh](#) &ms)  
*Constructor using a [Mesh](#) instance.*

*Return pointer to current side and move to next one (Non constant version)*
- [Side](#) \* [get](#) () const  
*Return pointer to current side and move to next one (Constant version)*

### 7.98.1 Detailed Description

Class to construct a list of sides having some common properties.

This class enables choosing multiple selection criteria by using function `select...`. However, the intersection of these properties must be empty.

Author

Rachid Touzani

Copyright

GNU Lesser Public License

### 7.98.2 Member Function Documentation

**void selectCode ( int *code*, int *dof* = 1 )**

Select sides having a given code for a given degree of freedom.

Parameters

in	<i>code</i>	Code that sides share
in	<i>dof</i>	Degree of Freedom label [Default: 1]

**void unselectCode ( int *code*, int *dof* = 1 )**

Unselect sides having a given code for a given degree of freedom.

Parameters

in	<i>code</i>	Code of sides to exclude
in	<i>dof</i>	Degree of Freedom label [Default: 1]

### 7.99.1 Detailed Description

**template<class T\_>class OFELI::SkMatrix< T\_ >**

To handle square matrices in skyline storage format.

This template class allows storing and manipulating a matrix in skyline storage format.

The matrix entries are stored in 2 vectors column by column as in the following example:

```

/      \      /      \
| 10      . |      | u0  u1  0  0  u7 |
| 11 12      . |      |      u2  u3  0  u8 |
| 0 13 14      . |      | ...      u4  u5  u9 |
| 0 0 15 16      |      |      u6  u10 |
| 17 18 19 110 111 |      |      u11 |
\      /      \      /

```

Template Parameters

<i>T_</i>	Data type (double, float, complex<double>, ...)

## 7.99.2 Constructor & Destructor Documentation

**SkMatrix ( )**

Default constructor.

Initializes a zero-dimension matrix

**SkMatrix ( *size\_t* size, *int* is\_diagonal = false )**

Constructor that initializes a dense symmetric matrix.

Normally, for a dense matrix this is not the right class.

Parameters

<i>in</i>	<i>size</i>	Number of matrix rows (and columns).
<i>in</i>	<i>is_diagonal</i>	Boolean to select if the matrix is diagonal or not [Default: false]

**SkMatrix ( *Mesh & mesh*, *size\_t* dof = 0, *int* is\_diagonal = false )**

Constructor using mesh to initialize skyline structure of matrix.

Parameters

<i>in</i>	<i>mesh</i>	<a href="#">Mesh</a> instance for which matrix graph is determined.
<i>in</i>	<i>dof</i>	Option parameter, with default value 0. dof=1 means that only one degree of freedom for each node (or element or side) is taken to determine matrix structure. The value dof=0 means that matrix structure is determined using all DOFs.
<i>in</i>	<i>is_diagonal</i>	Boolean argument to say is the matrix is actually a diagonal matrix or not.

**SkMatrix ( *const Vect< size\_t > & ColHt* )**

Constructor that initializes skyline structure of matrix using vector of column heights.

Parameters

<b>in</b>	<i>ColHt</i>	<a href="#">Vect</a> instance that contains rows lengths of matrix.
-----------	--------------	---

### 7.99.3 Member Function Documentation

**void setMesh ( Mesh & mesh, size\_t dof = 0 )**

Determine mesh graph and initialize matrix.

This member function is called by constructor with the same arguments

Parameters

<b>in</b>	<i>mesh</i>	<a href="#">Mesh</a> instance for which matrix graph is determined.
<b>in</b>	<i>dof</i>	Option parameter, with default value 0. dof=1 means that only one degree of freedom for each node (or element or side) is taken to determine matrix structure. The value dof=0 means that matrix structure is determined using all DOFs.

**void setSkyline ( Mesh & mesh )**

Determine matrix structure.

This member function calculates matrix structure using a [Mesh](#) instance.

Parameters

<b>in</b>	<i>mesh</i>	<a href="#">Mesh</a> instance
-----------	-------------	-------------------------------

**void setDOF ( size\_t i )**

Choose DOF to activate.

This function is available only if variable dof is equal to 1 in the constructor

Parameters

<b>in</b>	<i>i</i>	Index of the DOF
-----------	----------	------------------

**void set ( size\_t i, size\_t j, const T\_ & val ) [virtual]**

Assign a value to an entry of the matrix.

Parameters

<b>in</b>	<i>i</i>	Row index (starting at i=1)
<b>in</b>	<i>j</i>	Column index (starting at i=1)
<b>in</b>	<i>val</i>	Value to assign to entry a(i, j)

Implements [Matrix< T\\_ >](#).

**void Apxy ( T\_ a, const SkMatrix< T\_ > & m )**

Add to matrix the product of a matrix by a scalar.

Parameters

in	$a$	Scalar to premultiply
in	$m$	Matrix by which $a$ is multiplied. The result is added to current instance

**void Apxy ( T\_  $a$ , const Matrix< T\_ > \*  $m$  )** [virtual]

Add to matrix the product of a matrix by a scalar.

Parameters

in	$a$	Scalar to premultiply
in	$m$	Matrix by which $a$ is multiplied. The result is added to current instance

Implements [Matrix< T\\_ >](#).

**void MultAdd ( const Vect< T\_ > &  $x$ , Vect< T\_ > &  $y$  ) const** [virtual]

Multiply matrix by vector  $x$  and add to  $y$ .

Parameters

in	$x$	Vector to multiply by matrix
in,out	$y$	Vector to add to the result. $y$ contains on output the result.

Implements [Matrix< T\\_ >](#).

**void TMultAdd ( const Vect< T\_ > &  $x$ , Vect< T\_ > &  $y$  ) const**

Multiply transpose of matrix by vector  $x$  and add to  $y$ .

Parameters

in	$x$	Vector to multiply by matrix
in,out	$y$	Vector to add to the result. $y$ contains on output the result.

**void MultAdd ( T\_  $a$ , const Vect< T\_ > &  $x$ , Vect< T\_ > &  $y$  ) const** [virtual]

Multiply matrix by a vector and add to another one.

Parameters

in	$a$	Constant to multiply by matrix
in	$x$	Vector to multiply by matrix
in,out	$y$	Vector to add to the result. $y$ contains on output the result.

Implements [Matrix< T\\_ >](#).

**void Mult ( const Vect< T\_ > &  $x$ , Vect< T\_ > &  $y$  ) const** [virtual]

Multiply matrix by vector  $x$  and save in  $y$ .

Parameters

in	$x$	Vector to multiply by matrix
out	$y$	Vector that contains on output the result.

Implements [Matrix< T\\_ >](#).

**void TMult ( const Vect< T\_ > &  $x$ , Vect< T\_ > &  $y$  ) const** [virtual]

Multiply transpose of matrix by vector  $x$  and save in  $y$ .

Parameters

in	$x$	Vector to multiply by matrix
out	$y$	Vector that contains on output the result.

Implements [Matrix< T\\_ >](#).

**void add ( size\_t  $i$ , size\_t  $j$ , const T\_ &  $val$  )** [virtual]

Add a constant value to an entry of the matrix.

Parameters

in	$i$	Row index
in	$j$	Column index
in	$val$	Constant value to add to $a(i, j)$

Implements [Matrix< T\\_ >](#).

**size\_t getColHeight ( size\_t  $i$  ) const**

Return column height.

Column height at entry  $i$  is returned.

**T\_ operator() ( size\_t  $i$ , size\_t  $j$  ) const** [virtual]

Operator () (Constant version).

Parameters

in	$i$	Row index
in	$j$	Column index

Implements [Matrix< T\\_ >](#).

**T\_ & operator() ( size\_t  $i$ , size\_t  $j$  )** [virtual]

Operator () (Non constant version).

Parameters

in	$i$	Row index
in	$j$	Column index

Implements [Matrix< T\\_ >](#).

**void DiagPrescribe ( Mesh &  $mesh$ , Vect< T\_ > &  $b$ , const Vect< T\_ > &  $u$ , int  $flag = 0$  )**

Impose an essential boundary condition.

This member function modifies diagonal terms in matrix and terms in vector that correspond to degrees of freedom with nonzero code in order to impose a boundary condition. It can be modified by member function **setPenal(..)**.

Parameters

in	$mesh$	<a href="#">Mesh</a> instance from which information is extracted.
in	$b$	<a href="#">Vect</a> instance that contains right-hand side.
in	$u$	<a href="#">Vect</a> instance that contains imposed values at DOFs where they are to be imposed.

in	<i>flag</i>	Parameter to determine whether only the right-hand side is to be modified (dof>0) or both matrix and right-hand side (dof=0, default value).
----	-------------	---

**void DiagPrescribe ( Vect< T\_ > & b, const Vect< T\_ > & u, int flag = 0 )**

Impose an essential boundary condition using the [Mesh](#) instance provided by the constructor.

This member function modifies diagonal terms in matrix and terms in vector that correspond to degrees of freedom with nonzero code in order to impose a boundary condition. It can be modified by member function **setPenal(..)**.

Parameters

in	<i>b</i>	<a href="#">Vect</a> instance that contains right-hand side.
in	<i>u</i>	<a href="#">Vect</a> instance that contains imposed values at DOFs where they are to be imposed.
in	<i>flag</i>	Parameter to determine whether only the right-hand side is to be modified (dof>0) or both matrix and right-hand side (dof=0, default value).

**SkMatrix<T\_>& operator= ( const SkMatrix< T\_ > & m )**

Operator =.

Copy matrix *m* to current matrix instance.

**SkMatrix<T\_>& operator= ( const T\_ & x )**

Operator =.

define the matrix as a diagonal one with all diagonal entries equal to *x*.

**SkMatrix<T\_>& operator+= ( const SkMatrix< T\_ > & m )**

Operator +=.

Add matrix *m* to current matrix instance.

**SkMatrix<T\_>& operator+= ( const T\_ & x )**

Operator +=.

Add constant value *x* to matrix entries.

**SkMatrix<T\_>& operator\*= ( const T\_ & x )**

Operator \*.

Premultiply matrix entries by constant value *x*.

**int setLU ( )**

Factorize the matrix (LU factorization)

LU factorization of the matrix is realized. Note that since this is an in place factorization, the contents of the matrix are modified.

Returns

- 0 if factorization was normally performed,
- *n* if the *n*-th pivot is null.

## Remarks

A flag in this class indicates after factorization that this one has been realized, so that, if the member function solve is called after this no further factorization is done.

**int solve ( Vect< T\_ > & *b*, bool *fact* = *true* )** [virtual]

Solve linear system.

The linear system having the current instance as a matrix is solved by using the LU decomposition. Solution is thus realized after a factorization step and a forward/backward substitution step. The factorization step is realized only if this was not already done.

Note that this function modifies the matrix contents if a factorization is performed. Naturally, if the matrix has been modified after using this function, the user has to refactorize it using the function setLU. This is because the class has no non-expensive way to detect if the matrix has been modified. The function setLU realizes the factorization step only.

Parameters

in,out	<i>b</i>	Vect instance that contains right-hand side on input and solution on output.
in	<i>fact</i>	Set true if matrix is to be factorized (Default value), false if not

## Returns

- 0 if solution was normally performed,
- *n* if the *n*-th pivot is null.

Implements [Matrix< T\\_ >](#).

**int solve ( const Vect< T\_ > & *b*, Vect< T\_ > & *x*, bool *fact* = *true* )** [virtual]

Solve linear system.

The linear system having the current instance as a matrix is solved by using the LU decomposition. Solution is thus realized after a factorization step and a forward/backward substitution step. The factorization step is realized only if this was not already done.

Note that this function modifies the matrix contents if a factorization is performed. Naturally, if the matrix has been modified after using this function, the user has to refactorize it using the function setLU. This is because the class has no non-expensive way to detect if the matrix has been modified. The function setLU realizes the factorization step only.

Parameters

in	<i>b</i>	Vect instance that contains right-hand side.
out	<i>x</i>	Vect instance that contains solution
in	<i>fact</i>	Set true if matrix is to be factorized (Default value), false if not

## Returns

- 0 if solution was normally performed,
- *n* if the *n*-th pivot is null.

Implements [Matrix< T\\_ >](#).

**T\_\* get ( ) const**

Return C-Array.

Skyline of matrix is stored row by row.

### 7.100.1 Detailed Description

**template<class T\_>class OFELI::SkSMatrix< T\_ >**

To handle symmetric matrices in skyline storage format.

This template class allows storing and manipulating a symmetric matrix in skyline storage format.

The matrix entries are stored column by column as in the following example:

```

/
| a0  a1  0  0  a7 |
|   a2  a3  0  a8 |
|   ...  a4  a5  a9 |
|           a6  a10 |
|               a11 |
\

```

Template Parameters

<code>T_</code>	Data type (double, float, complex<double>, ...)
-----------------	---

Author

Rachid Touzani

Copyright

GNU Lesser Public License

### 7.100.2 Constructor & Destructor Documentation

**SkSMatrix ( )**

Default constructor.

Initializes a zero-dimension matrix

**SkSMatrix ( size\_t size, int is\_diagonal = false )**

Constructor that initializes a dense symmetric matrix.

Normally, for a dense matrix this is not the right class.

Parameters

in	<i>size</i>	Number of matrix rows (and columns).
in	<i>is_diagonal</i>	Boolean to select if the matrix is diagonal or not [Default: false]

**SkSMatrix ( Mesh & mesh, size\_t dof = 0, int is\_diagonal = false )**

Constructor using mesh to initialize skyline structure of matrix.

Parameters

in	<i>mesh</i>	<a href="#">Mesh</a> instance for which matrix graph is determined.
in	<i>dof</i>	Option parameter, with default value 0. dof=1 means that only one degree of freedom for each node (or element or side) is taken to determine matrix structure. The value dof=0 means that matrix structure is determined using all DOFs.
in	<i>is_diagonal</i>	Boolean argument to say is the matrix is actually a diagonal matrix or not.

**SkSMatrix ( const Vect< size\_t > & ColHt )**

Constructor that initializes skyline structure of matrix using vector of column height.

Parameters

in	<i>ColHt</i>	<a href="#">Vect</a> instance that contains rows lengths of matrix.
----	--------------	---

**SkSMatrix ( const Vect< size\_t > & I, const Vect< size\_t > & J, int opt = 1 )**

Constructor for a square matrix using non zero row and column indices.

Parameters

in	<i>I</i>	Vector containing row indices
in	<i>J</i>	Vector containing column indices
in	<i>opt</i>	Flag indicating if vectors I and J are cleaned and ordered (opt=1) or not (opt=0). In the latter case, these vectors can contain the same contents more than once and are not necessarily ordered.

**SkSMatrix ( const Vect< size\_t > & I, const Vect< size\_t > & J, const Vect< T\_ > & a, int opt = 1 )**

Constructor for a square matrix using non zero row and column indices.

Parameters

in	<i>I</i>	Vector containing row indices
in	<i>J</i>	Vector containing column indices
in	<i>a</i>	Vector containing matrix entries in the same order than the one given by I and J
in	<i>opt</i>	Flag indicating if vectors I and J are cleaned and ordered (opt=1) or not (opt=0). In the latter case, these vectors can contain the same contents more than once and are not necessarily ordered

### 7.100.3 Member Function Documentation

**void setMesh ( Mesh & mesh, size\_t dof = 0 )**

Determine mesh graph and initialize matrix.

This member function is called by constructor with the same arguments

Parameters

in	<i>mesh</i>	<a href="#">Mesh</a> instance for which matrix graph is determined.
in	<i>dof</i>	Option parameter, with default value 0. dof=1 means that only one degree of freedom for each node (or element or side) is taken to determine matrix structure. The value dof=0 means that matrix structure is determined using all DOFs.

**void setSkyline ( Mesh & mesh )**

Determine matrix structure.

This member function calculates matrix structure using [Mesh](#) instance mesh.

**void set ( size\_t i, size\_t j, const T\_ & val ) [virtual]**

Assign a value to an entry of the matrix.

Parameters

in	<i>i</i>	Row index
in	<i>j</i>	Column index
in	<i>val</i>	Value to assign to a(i,j)

Implements [Matrix< T\\_ >](#).

**void Axy ( T\_ a, const SkSMatrix< T\_ > & m )**

Add to matrix the product of a matrix by a scalar.

Parameters

in	<i>a</i>	Scalar to premultiply
in	<i>m</i>	Matrix by which a is multiplied. The result is added to current instance

**void Axy ( T\_ a, const Matrix< T\_ > \* m ) [virtual]**

Add to matrix the product of a matrix by a scalar.

Parameters

in	<i>a</i>	Scalar to premultiply
in	<i>m</i>	Pointer to Matrix by which a is multiplied. The result is added to current instance

Implements [Matrix< T\\_ >](#).

**void MultAdd ( const Vect< T\_ > & x, Vect< T\_ > & y ) const [virtual]**

Multiply matrix by vector x and add to y.

Parameters

in	$x$	Vector to multiply by matrix
in,out	$y$	Vector to add to the result. $y$ contains on output the result.

Implements [Matrix< T\\_ >](#).

**void MultAdd ( T\_  $a$ , const Vect< T\_ > &  $x$ , Vect< T\_ > &  $y$  ) const** [virtual]

Multiply matrix by vector  $a*x$  and add to  $y$ .

Parameters

in	$a$	Constant to multiply by matrix
in	$x$	Vector to multiply by matrix
in,out	$y$	Vector to add to the result. $y$ contains on output the result.

Implements [Matrix< T\\_ >](#).

**void Mult ( const Vect< T\_ > &  $x$ , Vect< T\_ > &  $y$  ) const** [virtual]

Multiply matrix by vector  $x$  and save in  $y$

Parameters

in	$x$	Vector to multiply by matrix
out	$y$	Vector that contains on output the result.

Implements [Matrix< T\\_ >](#).

**void TMult ( const Vect< T\_ > &  $x$ , Vect< T\_ > &  $y$  ) const** [virtual]

Multiply transpose of matrix by vector  $x$  and save in  $y$ .

Parameters

in	$x$	Vector to multiply by matrix
out	$y$	Vector that contains on output the result.

Implements [Matrix< T\\_ >](#).

**void add ( size.t  $i$ , size.t  $j$ , const T\_ &  $val$  )** [virtual]

Add a constant to an entry of the matrix.

Parameters

in	$i$	Row index
in	$j$	Column index
in	$val$	Constant value to add to $a(i,j)$

Implements [Matrix< T\\_ >](#).

**size.t getColHeight ( size.t  $i$  ) const**

Return column height.

Column height at entry  $i$  is returned.

**T& operator() ( size.t  $i$ , size.t  $j$  )** [virtual]

Operator () (Non constant version).

Parameters

<code>in</code>	<code>i</code>	Row index
<code>in</code>	<code>j</code>	Column index

Warning

To modify a value of an entry of the matrix it is safer not to modify both lower and upper triangles. Otherwise, wrong values will be assigned. If not sure, use the member functions `set` or `add`.

Implements [Matrix< T\\_ >](#).

**`T_ operator() ( size_t i, size_t j ) const`** [virtual]

Operator `()` (Constant version).

Parameters

<code>in</code>	<code>i</code>	Row index
<code>in</code>	<code>j</code>	Column index

Implements [Matrix< T\\_ >](#).

**`SksMatrix<T_>& operator= ( const SksMatrix< T_ > & m )`**

Operator `=`.

Copy matrix `m` to current matrix instance.

**`SksMatrix<T_>& operator= ( const T_ & x )`**

Operator `=`.

define the matrix as a diagonal one with all diagonal entries equal to `x`.

**`SksMatrix<T_>& operator+= ( const SksMatrix< T_ > & m )`**

Operator `+=`.

Add matrix `m` to current matrix instance.

**`SksMatrix<T_>& operator*= ( const T_ & x )`**

Operator `*=`.

Premultiply matrix entries by constant value `x`.

**`int setLDLt ( )`**

Factorize matrix (LDLt (Crout) factorization).

Returns

- 0 if factorization was normally performed
- `n` if the `n`-th pivot is null

**`int solveLDLt ( const Vect< T_ > & b, Vect< T_ > & x )`**

Solve a linear system using the LDLt (Crout) factorization.

This function solves a linear system. The LDLt factorization is performed if this was not already done using the function `setLU`.

Parameters

in	<i>b</i>	<a href="#">Vect</a> instance that contains right-hand side
out	<i>x</i>	<a href="#">Vect</a> instance that contains solution

Returns

- 0 if solution was normally performed,
  - *n* if the *n*-th pivot is null
- Solution is performed only if factorization has previously been invoked.

**int solve ( [Vect](#)< T\_ > & *b*, bool *fact* = *true* )** [virtual]

Solve linear system.

The linear system having the current instance as a matrix is solved by using the LDLt decomposition. Solution is thus realized after a factorization step and a forward/backward substitution step. The factorization step is realized only if this was not already done.

Note that this function modifies the matrix contents if a factorization is performed. Naturally, if the matrix has been modified after using this function, the user has to refactorize it using the function `setLU`. This is because the class has no non-expensive way to detect if the matrix has been modified. The function `setLDLt` realizes the factorization step only.

Parameters

in,out	<i>b</i>	<a href="#">Vect</a> instance that contains right-hand side on input and solution on output.
in	<i>fact</i>	Set true if matrix is to be factorized (Default value), false if not

Returns

- 0 if solution was normally performed,
- *n* if the *n*-th pivot is null.

Implements [Matrix](#)< T\_ >.

**int solve ( const [Vect](#)< T\_ > & *b*, [Vect](#)< T\_ > & *x*, bool *fact* = *true* )** [virtual]

Solve linear system.

The linear system having the current instance as a matrix is solved by using the LDLt decomposition. Solution is thus realized after a factorization step and a forward/backward substitution step. The factorization step is realized only if this was not already done.

Note that this function modifies the matrix contents if a factorization is performed. Naturally, if the matrix has been modified after using this function, the user has to refactorize it using the function `setLDLt`. This is because the class has no non-expensive way to detect if the matrix has been modified. The function `setLDLt` realizes the factorization step only.

Parameters

in	<i>b</i>	<a href="#">Vect</a> instance that contains right-hand side.
out	<i>x</i>	<a href="#">Vect</a> instance that contains solution
in	<i>fact</i>	Set true if matrix is to be factorized (Default value), false if not

Returns

- 0 if solution was normally performed,
- *n* if the *n*-th pivot is null.

Implements [Matrix](#)< T\_ >.

**T\_\* get ( ) const**

Return C-Array.

Skyline of matrix is stored row by row.

To store and treat a sphere.

### 7.101.2 Constructor & Destructor Documentation

**Sphere ( const Point< real.t > &c, real.t r, int code = 1 )**

Constructor.

Parameters

in	<i>c</i>	Coordinates of center of sphere
in	<i>r</i>	Radius
in	<i>code</i>	Code to assign to the generated sphere [Default: 1]

### 7.101.3 Member Function Documentation

**real.t getSignedDistance ( const Point< real.t > &p ) const** [virtual]

Return signed distance of a given point from the current sphere.

The computed distance is negative if p lies in the ball, positive if it is outside, and 0 on the sphere

Parameters

in	<i>p</i>	Point<double> instance
----	----------	------------------------

Reimplemented from [Figure](#).

**Sphere& operator+= ( Point< real.t > a )**

Operator +=.

Translate sphere by a vector a

**Sphere& operator+= ( real.t a )**

Operator \*+=.

Scale sphere by a factor a

### 7.102.1 Detailed Description

**template<class T\_>class OFELI::SpMatrix< T\_ >**

To handle matrices in sparse storage format.

This template class enables storing and manipulating a sparse matrix, i.e. only nonzero terms are stored. Internally, the matrix is stored as a vector instance and uses for the definition of its graph a `Vect<size_t>` instance `row_ptr` and a `Vect<size_t>` instance `col_ind` that contains respectively addresses of first element of each row and column indices.

To illustrate this, consider the matrix

$$\begin{pmatrix} 1 & 2 & 0 \\ 3 & 4 & 0 \\ 0 & 5 & 0 \end{pmatrix}$$

Such a matrix is stored in the `vector<real_t>` instance `{1,2,3,4,5}`. The vectors `row_ptr` and `col_ind` are respectively: `{0,2,4,5}`, `{1,2,1,2,2}`

When the library `eigen` is used in conjunction with `OFELI`, the class uses the sparse matrix class of `eigen` and enables then access to specific solvers (see class `LinearSolver`)

Template Parameters

<code>T_</code>	Data type (double, float, complex<double>, ...)

### 7.103.1 Detailed Description

Solver of the Steklov Poincare problem in 2-D geometries using piecewise constant boundary element.

[SteklovPoincare2DBE](#) solves the Steklov Poincare problem in 2-D: Given the trace of a harmonic function on the boundary of a given (inner or outer) domain, this class computes the normal derivative of the function. The normal is considered as oriented out of the bounded (inner) domain in both inner and outer configurations. The numerical approximation uses piecewise constant ( $P_0$ ) approximation on edges of the boundary. Solution is obtained from the GMRES iterative solver without preconditioning. The given data is the vector (instance of class [Vect](#)) of piecewise constant values of the harmonic function on the boundary and the returned solution is piecewise constant value of the normal derivative considered either as a [Vect](#) instance.

Note

Although the mesh of the inner domain is not necessary to solve the problem, this one must be provided in order to calculate the outward normal.

### 7.103.2 Constructor & Destructor Documentation

**SteklovPoincare2DBE ( Mesh & *ms* )**

Constructor using mesh data.

Parameters

<i>in</i>	<i>ms</i>	Reference to <a href="#">Mesh</a> instance.
-----------	-----------	---

**SteklovPoincare2DBE ( Mesh & *ms*, Vect< real\_t > & *u* )**

Constructor that solves the Steklov Poincare problem.

This constructor calls member function setMesh and Solve.

Parameters

<i>in</i>	<i>ms</i>	Reference to mesh instance.
<i>in</i>	<i>u</i>	Reference to solution vector. It contains the solution (normal derivative on boundary, once problem is solved

### 7.103.3 Member Function Documentation

**void setMesh ( Mesh & *ms* )**

set [Mesh](#) instance

Parameters

<i>in</i>	<i>ms</i>	<a href="#">Mesh</a> instance
-----------	-----------	-------------------------------

**void setExterior ( )**

Choose domain of the Laplace equation as exterior one.

By default the domain where the Laplace equation is considered is the interior domain, *i.e.* bounded. This function chooses the exterior of a bounded domain

**int run ( )**

Solve Setklov-Poincare problem.

This member function builds and solves the Steklov-Poincare equation.

## 7.104 Tabulation Class Reference

To read and manipulate tabulated functions.

### Public Member Functions

*Get the Number of read functions.*
- [size\\_t getNbVar](#) (size\_t n) const  
*Get number of variables of a given function.*
- [string getFuncName](#) (size\_t n) const  
*Get the name of a read function.*
- [size\\_t getSize](#) (size\_t n, size\_t i) const  
*Get number of points defining tabulation.*
- [real\\_t getMinVar](#) (size\_t n, size\_t i) const  
*Get minimal value of a variable.*
- [real\\_t getMaxVar](#) (size\_t n, size\_t i) const  
*Get maximal value of a variable.*

### 7.104.1 Detailed Description

To read and manipulate tabulated functions.

This class enables reading a tabulated function of one to three variables and calculating the value of the function using piecewise multilinear interpolation.

The file defining the function is an XML file where any function is introduced via the tag "`<Function`". The abscissae are uniformly distributed.

- **real\_t getMinEdgeLength** () const  
*Return minimal edge length of tetrahedron.*
- **std::vector**< **Point**< **real\_t** > > **DSH** () const  
*Calculate partial derivatives of shape functions at element nodes.*

### 7.105.1 Detailed Description

Defines a three-dimensional 4-node tetrahedral finite element using  $P_1$  interpolation.

The reference element is the right tetrahedron with four unit edges interpolation.

Author

Rachid Touzani

Copyright

GNU Lesser Public License

### 7.105.2 Member Function Documentation

**real\_t Sh** ( size\_t i, **Point**< **real\_t** > s ) const

Calculate shape function of node i at a given point s.  
s is a point in the reference tetrahedron.

**Point**<**real\_t**> **EdgeSh** ( size\_t k, **Point**< **real\_t** > s )

Return edge shape function.

Parameters

in	$k$	Local edge number for which the edge shape function is computed
in	$s$	Local coordinates in element

Remarks

[Element](#) edges are ordered as follows: [Edge](#)  $k$  has end vertices  $k$  and  $k+1$

**Point<real\_t> CurlEdgeSh ( size\_t  $k$  )**

Return curl of edge shape function.

Parameters

in	$k$	Local edge number for which the curl of the edge shape function is computed
----	-----	---

Remarks

[Element](#) edges are ordered as follows: [Edge](#)  $k$  has end vertices  $k$  and  $k+1$

**std::vector<Point<real\_t> > DSh ( ) const**

Calculate partial derivatives of shape functions at element nodes.

Returns

Vector of partial derivatives of shape functions *e.g.*  $dsh[i-1].x$ ,  $dsh[i-1].y$ , are partial derivatives of the  $i$ -th shape function

## 7.106 Timer Class Reference

To handle elapsed time counting.

### Public Member Functions

- [Timer](#) ()  
*Default constructor.*
- [~Timer](#) ()  
*Destructor.*
- bool [Started](#) () const  
*Say if time counter has started.*
- void [Start](#) ()  
*Start (or resume) time counting.*
- void [Stop](#) ()  
*Stop time counting.*
- void [Clear](#) ()  
*Clear time value (Set to zero)*
- [real\\_t](#) [get](#) () const  
*Return elapsed time (in seconds)*
- [real\\_t](#) [getTime](#) () const  
*Return elapsed time (in seconds)*

### 7.106.1 Detailed Description

To handle elapsed time counting.

This class is to be used when testing program performances. A normal usage of the class is, once an instance is constructed, to use alternatively, Start, Stop and Resume. Elapsed time can be obtained once the member function Stop is called.

Author

Rachid Touzani

Copyright

GNU Lesser Public License

### 7.106.2 Member Function Documentation

**bool Started ( ) const**

Say if time counter has started.

Return true if time has started, false if not

**void Start ( )**

Start (or resume) time counting.

This member function is to be used to start or resume time counting

**void Stop ( )**

Stop time counting.

This function interrupts time counting. This one can be resumed by the function Start

**real\_t getTime ( ) const**

Return elapsed time (in seconds)

Identical to get

## 7.107 TimeStepping Class Reference

To solve time stepping problems, i.e. systems of linear ordinary differential equations of the form  $[A2]\{y''\} + [A1]\{y'\} + [A0]\{y\} = \{b\}$ .

### Public Member Functions

- [TimeStepping](#) ()  
*Default constructor.*
- [TimeStepping](#) ([TimeScheme](#) s, [real\\_t](#) time\_step=[theTimeStep](#), [real\\_t](#) final\_time=[theFinalTime](#))  
*Constructor using time discretization data.*
- [~TimeStepping](#) ()  
*Destructor.*
- void [set](#) ([TimeScheme](#) s, [real\\_t](#) time\_step=[theTimeStep](#), [real\\_t](#) final\_time=[theFinalTime](#))  
*Define data of the differential equation or system.*
- void [setLinearSolver](#) ([LinearSolver](#)< [real\\_t](#) > &ls)

- Set reference to *LinearSolver* instance.

  - void `setPDE` (*Equa* &eq, bool nl=false)

Define partial differential equation to solve.
- void `setRK4RHS` (*Vect*< *real.t* > &f)

Set intermediate right-hand side vector for the Runge-Kutta method.
- void `setRK3_TVDRHS` (*Vect*< *real.t* > &f)

Set intermediate right-hand side vector for the TVD Runge-Kutta 3 method.
- void `setInitial` (*Vect*< *real.t* > &u)

Set initial condition for the system of differential equations.
- void `setInitial` (*Vect*< *real.t* > &u, *Vect*< *real.t* > &v)

Set initial condition for a system of differential equations.
- void `setInitialRHS` (*Vect*< *real.t* > &f)

Set initial RHS for a system of differential equations when the used scheme requires it.
- void `setRHS` (*Vect*< *real.t* > &b)

Set right-hand side vector.
- void `setRHS` (string exp)

Set right-hand side as defined by a regular expression.
- void `setBC` (*Vect*< *real.t* > &u)

Set vector containing boundary condition to enforce.
- void `setBC` (int code, string exp)

Set boundary condition as defined by a regular expression.
- void `setNewmarkParameters` (*real.t* beta, *real.t* gamma)

Define parameters for the Newmark scheme.
- void `setConstantMatrix` ()

Say that matrix problem is constant.
- void `setNonConstantMatrix` ()

Say that matrix problem is variable.
- void `setLinearSolver` (*Iteration* s=DIRECT\_SOLVER, *Preconditioner* p=DIAG\_PREC)

Set linear solver data.
- void `setNLTerm0` (*Vect*< *real.t* > &a0, *Matrix*< *real.t* > &A0)

Set vectors defining a nonlinear first order system of ODEs.
- void `setNLTerm` (*Vect*< *real.t* > &a0, *Vect*< *real.t* > &a1, *Vect*< *real.t* > &a2)

Set vectors defining a nonlinear second order system of ODEs.
- *real.t* `runOneTimeStep` ()

Run one time step.
- void `run` (bool opt=false)

Run the time stepping procedure.
- void `Assembly` (const *Element* &el, *real.t* \*b, *real.t* \*A0, *real.t* \*A1, *real.t* \*A2=nullptr)

Assemble element arrays into global matrix and right-hand side.
- void `SAssembly` (const *Side* &sd, *real.t* \*b, *real.t* \*A=nullptr)

Assemble side arrays into global matrix and right-hand side.
- *LinearSolver*< *real.t* > & `getLSolver` ()

Return *LinearSolver* instance.

### 7.107.1 Detailed Description

To solve time stepping problems, i.e. systems of linear ordinary differential equations of the form  $[A2]\{y''\} + [A1]\{y'\} + [A0]\{y\} = \{b\}$ .

Features:

- The system may be first or second order (first and/or second order time derivatives)
- The following time integration schemes can be used:
  - For first order systems: The following schemes are implemented Forward Euler (value↵ : *FORWARD\_EULER*)  
Backward Euler (value: *BACKWARD\_EULER*)  
Crank-Nicolson (value: *CRANK\_NICOLSON*)  
Heun (value: *HEUN*)  
2nd Order Adams-Bashforth (value: *AB2*)  
4-th order Runge-Kutta (value: *RK4*)  
2nd order Backward Differentiation Formula (value: *BDF2*)
  - For second order systems: The following schemes are implemented Newmark (value↵ : *NEWMARK*)

### 7.107.2 Constructor & Destructor Documentation

**TimeStepping ( TimeScheme s, real\_t time\_step = theTimeStep, real\_t final\_time = theFinalTime )**

Constructor using time discretization data.

Parameters

in	s	Choice of the scheme: To be chosen in the enumerated variable <i>TimeScheme</i> (see the presentation of the class)
in	time_step	Value of the time step. This value will be modified if an adaptive method is used. The default value for this parameter if the value given by the global variable theTimeStep
in	final_time	Value of the final time (time starts at 0). The default value for this parameter is the value given by the global variable theFinalTime

### 7.107.3 Member Function Documentation

**void set ( TimeScheme s, real\_t time\_step = theTimeStep, real\_t final\_time = theFinalTime )**

Define data of the differential equation or system.

Parameters

in	<i>s</i>	Choice of the scheme: To be chosen in the enumerated variable <i>TimeScheme</i> (see the presentation of the class)
in	<i>time_step</i>	Value of the time step. This value will be modified if an adaptive method is used. The default value for this parameter is the value given by the global variable <code>theTimeStep</code>
in	<i>final_time</i>	Value of the final time (time starts at 0). The default value for this parameter is the value given by the global variable <code>theFinalTime</code>

**void setLinearSolver ( LinearSolver< real\_t > & ls )**

Set reference to [LinearSolver](#) instance.

Parameters

in	<i>ls</i>	Reference to <a href="#">LinearSolver</a> instance
----	-----------	--

**void setPDE ( Equa & eq, bool nl = false )**

Define partial differential equation to solve.

The used equation class must have been constructed using the [Mesh](#) instance

Parameters

in	<i>eq</i>	Reference to equation instance
in	<i>nl</i>	Toggle to say if the considered equation is linear [Default: 0] or not

**void setRK4RHS ( Vect< real\_t > & f )**

Set intermediate right-hand side vector for the Runge-Kutta method.

Parameters

in	<i>f</i>	Vector containing the RHS
----	----------	---------------------------

**void setRK3\_TVDRHS ( Vect< real\_t > & f )**

Set intermediate right-hand side vector for the TVD Runge-Kutta 3 method.

Parameters

in	<i>f</i>	Vector containing the RHS
----	----------	---------------------------

**void setInitial ( Vect< real\_t > & u )**

Set initial condition for the system of differential equations.

Parameters

in	<i>u</i>	Vector containing initial condition for the unknown
----	----------	---

Remarks

If a second-order differential equation is to be solved, use the the same function with two initial vectors (one for the unknown, the second for its time derivative)

**void setInitial ( Vect< real\_t > &  $u$ , Vect< real\_t > &  $v$  )**

Set initial condition for a system of differential equations.

## Parameters

in	$u$	Vector containing initial condition for the unknown
in	$v$	Vector containing initial condition for the time derivative of the unknown

## Note

This function can be used to provide solution at previous time step if a restarting procedure is used.

This member function is to be used only in the case of a second order system

**void setInitialRHS ( Vect< real.t > &f )**

Set initial RHS for a system of differential equations when the used scheme requires it.

Giving the right-hand side at initial time is sometimes required for high order methods like Runge-Kutta

## Parameters

in	$f$	Vector containing right-hand side at initial time. This vector is helpful for high order methods
----	-----	--

## Note

This function can be used to provide solution at previous time step if a restarting procedure is used.

**void setRHS ( string exp )**

Set right-hand side as defined by a regular expression.

## Parameters

in	$exp$	Regular expression as a function of x, y, z and t
----	-------	---

**void setBC ( int code, string exp )**

Set boundary condition as defined by a regular expression.

## Parameters

in	$code$	Code for which expression is assigned
in	$exp$	Regular expression to assign as a function of x, y, z and t

**void setNewmarkParameters ( real.t beta, real.t gamma )**

Define parameters for the Newmark scheme.

## Parameters

in	$beta$	Parameter beta [Default: 0.25]
in	$gamma$	Parameter gamma [Default: 0.5]

**void setConstantMatrix ( )**

Say that matrix problem is constant.

This is useful if the linear system is solved by a factorization method but has no effect otherwise

**void setNonConstantMatrix ( )**

Say that matrix problem is variable.

This is useful if the linear system is solved by a factorization method but has no effect otherwise

**void setLinearSolver ( Iteration  $s$  = DIRECT\_SOLVER, Preconditioner  $p$  = DIAG\_PREC )**

Set linear solver data.

Parameters

in	$s$	Solver identification parameter. To be chosen in the enumeration variable Iteration: DIRECT_SOLVER, CG_SOLVER, CGS_SOLVER, BICG_SOLVER, BICG_STAB_SOLVER, GMRES_SOLVER, QMR_SOLVE← R [Default: DIRECT_SOLVER]
in	$p$	Preconditioner identification parameter. To be chosen in the enumeration variable Preconditioner: IDENT_PREC, DIAG_PREC, ILU_PREC [Default: DIAG_PREC]

Note

The argument  $p$  has no effect if the solver is DIRECT\_SOLVER

**void setNLTerm0 ( Vect< real.t > &  $a0$ , Matrix< real.t > &  $A0$  )**

Set vectors defining a nonlinear first order system of ODEs.

The ODE system has the form  $a1(u)' + a0(u) = 0$

Parameters

in	$a0$	Reference to <a href="#">Vect</a> instance defining the 0-th order term
in	$A0$	Reference to <a href="#">Matrix</a> instance

**void setNLTerm ( Vect< real.t > &  $a0$ , Vect< real.t > &  $a1$ , Vect< real.t > &  $a2$  )**

Set vectors defining a nonlinear second order system of ODEs.

The ODE system has the form  $a2(u)'' + a1(u)' + a0(u) = 0$

Parameters

in	$a0$	Reference to <a href="#">Vect</a> instance defining the 0-th order term
in	$a1$	Reference to <a href="#">Vect</a> instance defining the first order term
in	$a2$	Reference to <a href="#">Vect</a> instance defining the second order term

**real.t runOneTimeStep ( )**

Run one time step.

Returns

Value of new time step if this one is updated

**void run ( bool  $opt$  = false )**

Run the time stepping procedure.

## Parameters

in	<i>opt</i>	Flag to say if problem matrix is constant while time stepping (true) or not (Default value is false)
----	------------	--

## Note

This argument is not used if the time stepping scheme is explicit

**void Assembly ( const Element & *el*, real\_t \* *b*, real\_t \* *A0*, real\_t \* *A1*, real\_t \* *A2* = *nullptr* )**

Assemble element arrays into global matrix and right-hand side.

This member function is to be called from finite element equation classes

## Parameters

in	<i>el</i>	Reference to <a href="#">Element</a> class
in	<i>b</i>	Pointer to element right-hand side
in	<i>A0</i>	Pointer to matrix of 0-th order term (involving no time derivative)
in	<i>A1</i>	Pointer to matrix of first order term (involving time first derivative)
in	<i>A2</i>	Pointer to matrix of second order term (involving time second derivative) [Default: <i>nullptr</i> ]

**void SAssembly ( const Side & *sd*, real\_t \* *b*, real\_t \* *A* = *nullptr* )**

Assemble side arrays into global matrix and right-hand side.

This member function is to be called from finite element equation classes

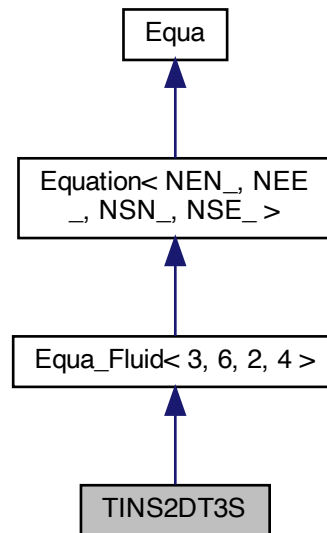

## Parameters

in	<i>sd</i>	Reference to <a href="#">Side</a> class
in	<i>b</i>	Pointer to side right-hand side
in	<i>A</i>	Pointer to matrix [Default: <i>nullptr</i> ]

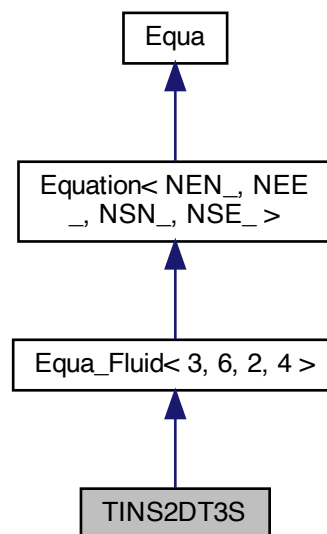

## 7.108 TINS2DT3S Class Reference

Builds finite element arrays for transient incompressible fluid flow using Navier-Stokes equations in 2-D domains. Numerical approximation uses stabilized 3-node triangle finite elements for velocity and pressure. 2nd-order projection scheme is used for time integration.

### 7.110.2 Constructor & Destructor Documentation

**Triang3** ( const **Element** \* *el* )

Constructor for an element.

The constructed triangle is an element in a 2-D mesh.

**Triang3** ( const **Side** \* *sd* )

Constructor for a side.

The constructed triangle is a side in a 3-D mesh.

**7.110.3 Member Function Documentation****real\_t Sh ( size\_t *i*, Point< real\_t > *s* ) const**

Calculate shape function of node at a given point.

Parameters

in	$i$	Label (local) of node
in	$s$	Natural coordinates of node where to evaluate

**std::vector<Point<real\_t> > DSh ( ) const**

Return partial derivatives of shape functions of element nodes.

Returns

Vector of partial derivatives of shape functions *e.g.* dsh[i-1].x, dsh[i-1].y, are partial derivatives of the  $i$ -th shape function.

**real\_t check ( ) const**

Check element area and number of nodes.

Returns

- $> 0$ :  $m$  is the length
- $= 0$ : zero length ( $\Rightarrow$  Error)

**Point<real\_t> Grad ( const LocalVect< real\_t, 3 > &  $u$  ) const**

Return constant gradient vector in triangle.

Parameters

in	$u$	Local vector for which the gradient is evaluated
----	-----	--

## 7.111 Triang6S Class Reference

### 7.111.1 Detailed Description

Defines a 6-Node straight triangular finite element using  $P_2$  interpolation.

The reference element is the rectangle triangle with two unit edges.

Author

Rachid Touzani

Copyright

GNU Lesser Public License

### 7.111.2 Constructor & Destructor Documentation

**Triang6S ( const Element \* *el* )**

Constructor for an element.

The constructed triangle is an element in a 2-D mesh.

Parameters

in	<i>el</i>	Pointer to <a href="#">Element</a> instance
----	-----------	---

### 7.111.3 Member Function Documentation

**void Sh ( real.t *s*, real.t *t*, real.t \* *sh* ) const**

Calculate shape functions.

Parameters

in	<i>s</i>	Local first coordinate of the point where the gradient of the shape functions are evaluated
in	<i>t</i>	Local second coordinate of the point where the gradient of the shape functions are evaluated
out	<i>sh</i>	Array of of shape functions at (s,t)

**void setLocal ( real.t *s*, real.t *t* )**

Initialize local point coordinates in element.

Parameters

in	<i>s</i>	Local first coordinate of the point where the gradient of the shape functions are evaluated
in	<i>t</i>	Local second coordinate of the point where the gradient of the shape functions are evaluated

**void atMidEdges ( std::vector< Point< real.t > > & *dsh*, std::vector< real.t > & *w* )**

Compute partial derivatives of shape functions at mid edges of triangles.

This member function can be called for integrations using partial derivatives of shape functions and approximated by midedge integration formula

Parameters

out	<i>dsh</i>	Vector containing partial derivatives of shape functions
out	<i>w</i>	Vector containing weights for the integration formula

**`std::vector<Point<real_t>> DSh ( ) const`**

Return partial derivatives of shape functions of element nodes.

Returns

[LocalVect](#) instance of partial derivatives of shape functions *e.g.* `dsh(i).x`, `dsh(i).y`, are partial derivatives of the *i*-th shape function.

Note

The local point at which the derivatives are computed must be chosen before by using the member function `setLocal`

## 7.112 Triangle Class Reference

*Operator +=.*

- `Triangle` & `operator+=` (`real_t` `a`)

*Operator \*+=.*

### 7.112.1 Detailed Description

To store and treat a triangle.

### 7.112.2 Constructor & Destructor Documentation

`Triangle ( )`

Default constructor.

Constructs a unit triangle with vertices (0,0), (1,0) and (0,1)

`Triangle ( const Point< real_t > &v1, const Point< real_t > &v2, const Point< real_t > &v3, int code = 1 )`

Constructor with vertices and code.

Parameters

in	<i>v1</i>	Coordinates of first vertex of triangle
in	<i>v2</i>	Coordinates of second vertex of triangle
in	<i>v3</i>	Coordinates of third vertex of triangle
in	<i>code</i>	Code to assign to the generated figure [Default: 1]

Remarks

Vertices must be given in counterclockwise order

### 7.112.3 Member Function Documentation

`real_t` `getSignedDistance` ( const `Point`< `real_t` > &*p* ) const [virtual]

Return signed distance of a given point from the current triangle.

The computed distance is negative if *p* lies in the triangle, positive if it is outside, and 0 on its boundary

Parameters

in	<i>p</i>	Point<double> instance
----	----------	------------------------

Reimplemented from [Figure](#).

**Triangle& operator+= ( Point< real\_t > a )**

Operator +=.

Translate triangle by a vector a

**Triangle& operator+= ( real\_t a )**

Operator \*+=.

Scale triangle by a factor a

### 7.114.1 Detailed Description

**template<class T\_>class OFELI::TrMatrix< T\_ >**

To handle tridiagonal matrices.

This class enables storing and manipulating tridiagonal matrices. The template parameter is the type of matrix entries. Any matrix entry can be accessed by the () operator: For instance, if A is an instance of this class, A(i, j) stands for the entry at the i-th row and j-th column, i and j starting from 1. If is difference from i-1, i or i+1, the returned value is 0. Entries of A can be assigned a value by the same operator. Only nonzero entries can be assigned.

Template Parameters

T_	Data type (double, float, complex<double>, ...)

- `T_ operator() (size_t i, size_t j) const`  
*Operator () with 2-D indexing (Constant version).*
- `T_ & operator() (size_t i, size_t j, size_t k)`  
*Operator () with 3-D indexing (Non constant version).*
- `T_ operator() (size_t i, size_t j, size_t k) const`  
*Operator () with 3-D indexing (Constant version).*
- `T_ & operator() (size_t i, size_t j, size_t k, size_t l)`  
*Operator () with 4-D indexing (Non constant version).*
- `T_ operator() (size_t i, size_t j, size_t k, size_t l) const`  
*Operator () with 4-D indexing (Constant version).*
- `Vect< T_ > & operator= (const Vect< T_ > &v)`  
*Operator = between vectors.*
- `void operator= (string s)`  
*Operator =*
- `void setUniform (T_ vmin, T_ vmax, size_t n)`  
*Initialize vector entries by setting extremal values and interval.*
- `Vect< T_ > & operator= (const T_ &a)`  
*Operator =*
- `Vect< T_ > & operator+= (const Vect< T_ > &v)`  
*Operator +=*
- `Vect< T_ > & operator+= (const T_ &a)`  
*Operator +=*
- `Vect< T_ > & operator-= (const Vect< T_ > &v)`  
*Operator -=*
- `Vect< T_ > & operator-= (const T_ &a)`  
*Operator -=*

- `Vect< T_ > & operator*=(const T_ &a)`  
*Operator \*=*
- `Vect< T_ > & operator/=(const T_ &a)`  
*Operator /=*
- `void push.back (const T_ &v)`  
*Add an entry to the vector.*
- `const Mesh & getMeshPtr () const`  
*Return reference to `Mesh` instance.*
- `T_ operator, (const Vect< T_ > &v) const`  
*Return Dot (scalar) product of two vectors.*
- `Vect< complex_t > getFFT ()`  
*Compute FFT transform of vector.*
- `Vect< complex_t > getInvFFT ()`  
*Compute Inverse FFT transform of vector.*

### 7.115.1 Detailed Description

`template<class T_>class OFELI::Vect< T_ >`

To handle general purpose vectors.

Author

Rachid Touzani

Copyright

GNU Lesser Public License

This template class enables defining and manipulating vectors of various data types. It inherits from the class `std::vector`. An instance of class `Vect` can be:

- A simple vector of given size
- A vector with up to three indices, *i.e.*, an entry of the vector can be `a(i)`, `a(i, j)` or `a(i, j, k)`. This feature is useful, for instance, in the case of a structured grid
- A vector associate to a finite element mesh. In this case, a constructor uses a reference to the `Mesh` instance. The size of the vector is by default equal to the number of nodes x the number of degrees of freedom by node. If the degrees of freedom are supported by elements or sides, then the vector is sized accordingly

Operators `=`, `[]` and `()` are overloaded so that one can write for instance:

```
Vect<real_t> u(10), v(10);
v = -1.0;
u = v;
u(3) = -2.0;
```

to set vector `v` entries to `-1`, copy vector `v` into vector `u` and assign third entry of `v` to `-2`. Note that entries of `v` are here `v(1)`, `v(2)`, ..., `v(10)`, *i.e.* vector entries start at index 1.

## Template Parameters

<i>T_</i>	Data type (real_t, float, complex<real_t>, ...)
-----------	---

**7.115.2 Constructor & Destructor Documentation****Vect ( size\_t *n* )**

Constructor setting vector size.

## Parameters

<i>in</i>	<i>n</i>	Size of vector
-----------	----------	----------------

**Vect ( size\_t *nx*, size\_t *ny* )**

Constructor of a 2-D index vector.

This constructor can be used for instance for a 2-D grid vector

## Parameters

<i>in</i>	<i>nx</i>	Size for the first index
<i>in</i>	<i>ny</i>	Size for the second index

## Remarks

The size of resulting vector is nx\*ny

**Vect ( size\_t *nx*, size\_t *ny*, size\_t *nz* )**

Constructor of a 3-D index vector.

This constructor can be used for instance for a 3-D grid vector

## Parameters

<i>in</i>	<i>nx</i>	Size for the first index
<i>in</i>	<i>ny</i>	Size for the second index
<i>in</i>	<i>nz</i>	Size for the third index

## Remarks

The size of resulting vector is nx\*ny\*nz

**Vect ( size\_t *nx*, size\_t *ny*, size\_t *nz*, size\_t *nt* )**

Constructor of a 4-D index vector.

This constructor can be used for instance for a 4-D grid vector

## Parameters

<i>in</i>	<i>nx</i>	Size for the first index
<i>in</i>	<i>ny</i>	Size for the second index
<i>in</i>	<i>nz</i>	Size for the third index

in	<i>nt</i>	Size for the fourth index
----	-----------	---------------------------

## Remarks

The size of resulting vector is  $nx*ny*nz*nt$

**Vect ( size\_t *n*, T\_ \* *x* )**

Create an instance of class [Vect](#) as an image of a C/C++ array.

Parameters

in	<i>n</i>	Dimension of vector to construct
in	<i>x</i>	C-array to copy

**Vect ( Grid & *g* )**

Constructor with a [Grid](#) instance.

The constructed vector has as size the total number of grid nodes

Parameters

in	<i>g</i>	<a href="#">Grid</a> instance
----	----------	-------------------------------

**Vect ( Mesh & *m*, DOFSupport *dof\_type* = NODE\_DOF, int *nb\_dof* = 0 )**

Constructor with a mesh instance.

Parameters

in	<i>m</i>	<a href="#">Mesh</a> instance
in	<i>dof_type</i>	Type of degrees of freedom. To be given among the enumerated values: NODE_DOF, ELEMENT_DOF, SIDE_DOF or EDGE_DOF (Default↵ : NODE_DOF)
in	<i>nb_dof</i>	Number of degrees of freedom per node, element or side If <i>nb_dof</i> is set to 0 (default value) the constructor picks this number from the <a href="#">Mesh</a> instance

**Vect ( Mesh & *m*, DOFSupport *dof\_type*, string *name*, int *nb\_dof* = 0, real\_t *t* = 0.0 )**

Constructor with a mesh instance giving name and time for vector.

Parameters

in	<i>m</i>	<a href="#">Mesh</a> instance
in	<i>dof_type</i>	Type of degrees of freedom. To be given among the enumerated values: NODE_DOF, ELEMENT_DOF, SIDE_DOF or EDGE_DOF
in	<i>name</i>	Name of the vector
in	<i>nb_dof</i>	Number of degrees of freedom per node, element or side If <i>nb↵_dof</i> is set to 0 the constructor picks this number from the <a href="#">Mesh</a> instance

in	<i>t</i>	Time value for the vector [Default 0.0]
----	----------	---

**Vect ( const Element \* *el*, const Vect< T\_ > & *v* )**

Constructor of an element vector.

The constructed vector has local numbering of nodes

Parameters

in	<i>el</i>	Pointer to <a href="#">Element</a> to localize
in	<i>v</i>	Global vector to localize

**Vect ( const Side \* *sd*, const Vect< T\_ > & *v* )**

Constructor of a side vector.

The constructed vector has local numbering of nodes

Parameters

in	<i>sd</i>	Pointer to <a href="#">Side</a> to localize
in	<i>v</i>	Global vector to localize

**Vect ( const Vect< T\_ > & *v*, const Vect< T\_ > & *bc* )**

Constructor using boundary conditions.

Boundary condition values contained in *bc* are reported to vector *v*

Parameters

in	<i>v</i>	<a href="#">Vect</a> instance to update
in	<i>bc</i>	<a href="#">Vect</a> instance containing imposed valued at desired DOF

**Vect ( const Vect< T\_ > & *v*, size\_t *nb\_dof*, size\_t *first\_dof* )**

Constructor to select some components of a given vector.

Parameters

in	<i>v</i>	<a href="#">Vect</a> instance to extract from
in	<i>nb_dof</i>	Number of DOF to extract
in	<i>first_dof</i>	First DOF to extract For instance, a choice <i>first_dof</i> =2 and <i>nb_dof</i> =1 means that the second DOF of each node is copied in the vector

**Vect ( const Vect< T\_ > & *v*, size\_t *n* )**

Constructor to select one component from a given 2 or 3-component vector.

Parameters

in	<i>v</i>	<a href="#">Vect</a> instance to extract from
in	<i>n</i>	Component to extract (must be > 1 and < 4 or).

**Vect ( size\_t *d*, const Vect< T\_ > & *v*, const string & *name* = " " )**

Constructor that extracts some degrees of freedom (components) from given instance of [Vect](#).

This constructor enables constructing a subvector of a given [Vect](#) instance. It selects a given list of degrees of freedom and put it according to a given order in the instance to construct.

Parameters

in	<i>d</i>	Integer number giving the list of degrees of freedom. This number is made of <i>n</i> digits where <i>n</i> is the number of degrees of freedom. Let us give an example: Assume that the instance <i>v</i> has 3 DOF by entity (node, element or side). The choice <i>d</i> =201 means that the constructed instance has 2 DOF where the first DOF is the third one of <i>v</i> , and the second DOF is the first one of <i>v</i> . Consequently, no digit can be larger than the number of DOF the constructed instance. In this example, a choice <i>d</i> =103 would produce an error message.
in	<i>v</i>	<a href="#">Vect</a> instance from which extraction is performed.
in	<i>name</i>	Name to assign to vector instance (Default value is " ").

Warning

Don't give zeros as first digits for the argument *d*. The number is in this case interpreted as octal !!

### 7.115.3 Member Function Documentation

**void set ( const T\_ \* *v*, size\_t *n* )**

Initialize vector with a c-array.

Parameters

in	<i>v</i>	c-array (pointer) to initialize <a href="#">Vect</a>
in	<i>n</i>	size of array

**void select ( const Vect< T\_ > & *v*, size\_t *nb\_dof* = 0, size\_t *first\_dof* = 1 )**

Initialize vector with another [Vect](#) instance.

Parameters

in	<i>v</i>	<a href="#">Vect</a> instance to extract from
in	<i>nb_dof</i>	Number of DOF per node, element or side (By default, 0: Number of degrees of freedom extracted from the <a href="#">Mesh</a> instance)
in	<i>first_dof</i>	First DOF to extract (Default: 1) For instance, a choice <i>first_dof</i> =2 and <i>nb_dof</i> =1 means that the second DOF of each node is copied in the vector

**void set ( const string & *exp*, size\_t *dof* = 1 )**

Initialize vector with an algebraic expression.

This function is to be used is a [Mesh](#) instance is associated to the vector

## Parameters

in	<i>exp</i>	Regular algebraic expression that defines a function of $x$ , $y$ , $z$ which are coordinates of nodes and $t$ which is the time value.
in	<i>dof</i>	Degree of freedom to which the value is assigned [Default: 1]

## Warning

If the time variable  $t$  is involved in the expression, the time value associated to the vector instance must be defined (Default value is 0) either by using the appropriate constructor or by the member function setTime.

**void set ( const string & exp, const Vect< real.t > & x )**

Initialize vector with an algebraic expression.

This function can be used for instance in 1-D

## Parameters

in	<i>exp</i>	Regular algebraic expression that defines a function of $x$ which are values of vector. This expression must use the variable $x$ as coordinate of vector.
----	------------	--

## Warning

If the time variable  $t$  is involved in the expression, the time value associated to the vector instance must be defined (Default value is 0) either by using the appropriate constructor or by the member function setTime.

## Parameters

in	$x$	Vector that defines coordinates
----	-----	---------------------------------

**void set ( Mesh & ms, const string & exp, size\_t dof = 1 )**

Initialize vector with an algebraic expression with providing mesh data.

## Parameters

in	<i>ms</i>	<a href="#">Mesh</a> instance
in	<i>exp</i>	Regular algebraic expression that defines a function of $x$ , $y$ and $z$ which are coordinates of nodes.
in	<i>dof</i>	Degree of freedom to which the value is assigned [Default: 1]

**void set ( const Vect< real.t > & x, const string & exp )**

Initialize vector with an algebraic expression.

## Parameters

in	$x$	<a href="#">Vect</a> instance that contains coordinates of points
in	<i>exp</i>	Regular algebraic expression that defines a function of $x$ and $i$ which are coordinates. Consider for instance that we want to initialize the <a href="#">Vect</a> instance with the values $v[i] = \exp(1+x[i])$ ; then, we use this member function as follows <code>v.set("exp("1+x",x);</code>

**void setMesh ( Mesh & *m*, DOFSupport *dof\_type* = *NODE\_DOF*, size\_t *nb\_dof* = 0 )**

Define mesh class to size vector.

Parameters

in	<i>m</i>	<a href="#">Mesh</a> instance
in	<i>dof_type</i>	Parameter to precise the type of degrees of freedom. To be chosen among the enumerated values: NODE.DOF, ELEMENT.DOF, SIDE.DOF, EDGE.DOF [Default: NODE.DOF]
in	<i>nb_dof</i>	Number of degrees of freedom per node, element or side. If <i>nb_dof</i> is set to 0 the constructor picks this number from the <a href="#">Mesh</a> instance [Default: 0]

**void setGrid ( Grid & g )**

Define grid class to size vector.

Parameters

in	<i>g</i>	<a href="#">Grid</a> instance
----	----------	-------------------------------

**void setSize ( size\_t nx, size\_t ny = 1, size\_t nz = 1, size\_t nt = 1 )**

Set vector size (for 1-D, 2-D or 3-D cases and 3-D + time)

This function allocates memory for the vector but does not initialize its components

Parameters

in	<i>nx</i>	Number of grid points in x-direction
in	<i>ny</i>	Number of grid points in y-direction [Default: 1]
in	<i>nz</i>	Number of grid points in z-direction [Default: 1]
in	<i>nt</i>	Number of grid points in t-direction [Default: 1]

**void resize ( size\_t n )**

Set vector size.

This function allocates memory for the vector but does not initialize its components

Parameters

in	<i>n</i>	Size of vector
----	----------	----------------

**void resize ( size\_t n, T\_ v )**

Set vector size and initialize to a constant value.

This function allocates memory for the vector

Parameters

in	<i>n</i>	Size of vector
in	<i>v</i>	Value to assign to vector entries

**void setDOFType ( DOFSupport dof\_type )**

Set DOF type of vector.

The DOF type combined with number of DOF per component enable determining the size of vector

Parameters

<b>in</b>	<i>dof_type</i>	Type of degrees of freedom. Value to be chosen among the enumerated values: NODE_DOF, ELEMENT_DOF, SIDE_DOF or EDGE_DOF
-----------	-----------------	---

**void setDG ( int *degree* = 1 )**

Set Discontinuous Galerkin type vector.

When the vector is associated to a mesh, this one is sized differently if the [DG](#) method is used.

Parameters

<b>in</b>	<i>degree</i>	Polynomial degree of the <a href="#">DG</a> method [Default: 1]
-----------	---------------	---

**bool isGrid ( ) const**

Say if vector is constructed for a grid.

Vectors constructed for grids are defined with the help of a [Grid](#) instance

Returns

true if vector is constructed with a [Grid](#) instance

**bool WithMesh ( ) const**

Return true if vector contains a [Mesh](#) pointer, false if not.

A [Vect](#) instance can be constructed using mesh information

**DOFSupport getDOFType ( ) const**

Return DOF type of vector

Returns

*dof\_type* Type of degrees of freedom. Value among the enumerated values: NODE\_DOF, ELEMENT\_DOF, SIDE\_DOF or EDGE\_DOF

**real\_t Norm ( NormType *t* ) const**

Compute a norm of vector.

Parameters

<b>in</b>	<i>t</i>	Norm type to compute: To choose among enumerate values: NORM1: 1-norm WNORM1: Weighted 1-norm (Discrete L1-norm) NORM2: 2-norm WNORM2: Weighted 2-norm (Discrete L2-norm) NORM_MAX: max norm (Infinity norm)
-----------	----------	--

Returns

Value of norm

Warning

This function is available for real valued vectors only

**real\_t getNorm1 ( ) const**

Calculate 1-norm of vector.

Remarks

This function is available only if the template parameter is double or complex<double>

**real\_t getNorm2 ( ) const**

Calculate 2-norm (Euclidean norm) of vector.

Remarks

This function is available only if the template parameter is double or complex<double>

**real\_t getNormMax ( ) const**

Calculate Max-norm (Infinite norm) of vector.

Remarks

This function is available only if the template parameter is double or complex<double>

**real\_t getWNorm2 ( ) const**

Calculate weighted 2-norm of vector.

The weighted 2-norm is the 2-Norm of the vector divided by the square root of its size

**void setIJK ( const string & exp )**

Assign a given function (given by an interpretable algebraic expression) of indices components of vector.

This function enable assigning a value to vector entries as function of indices

Parameters

<i>in</i>	<i>exp</i>	Regular algebraic expression to assign. It must involve the variables i, j and/or k.
-----------	------------	--

**void setIJKL ( const string & exp )**

Assign a given function (given by an interpretable algebraic expression) of indices components of vector.

This function enable assigning a value to vector entries as function of indices

Parameters

<i>in</i>	<i>exp</i>	Regular algebraic expression to assign. It must involve the variables i, j, k and/or l.
-----------	------------	---

**void setNodeBC ( Mesh & m, int code, T\_ val, size\_t dof )**

Assign a given value to components of vector with given code.

Vector components are assumed nodewise

Parameters

in	<i>m</i>	<a href="#">Mesh</a> instance
in	<i>code</i>	The value is assigned if the node has this code
in	<i>val</i>	Value to assign
in	<i>dof</i>	Degree of freedom to assign

**void setNodeBC ( Mesh & *m*, int *code*, T\_ *val* )**

Assign a given value to components of vector with given code.

Vector components are assumed nodewise. Here all dofs of nodes with given code will be assigned

Parameters

in	<i>m</i>	<a href="#">Mesh</a> instance
in	<i>code</i>	The value is assigned if the node has this code
in	<i>val</i>	Value to assign

**void setSideBC ( Mesh & *m*, int *code*, T\_ *val*, size\_t *dof* )**

Assign a given value to components of vector corresponding to sides with given code.

Vector components are assumed nodewise

Parameters

in	<i>m</i>	Instance of mesh
in	<i>code</i>	Code for which nodes will be assigned prescribed value
in	<i>val</i>	Value to prescribe
in	<i>dof</i>	Degree of Freedom for which the value is assigned [default: 1]

**void setNodeBC ( Mesh & *m*, int *code*, const string & *exp*, size\_t *dof* )**

Assign a given function (given by an interpretable algebraic expression) to components of vector with given code.

Vector components are assumed nodewise

Parameters

in	<i>m</i>	Instance of mesh
in	<i>code</i>	Code for which nodes will be assigned prescribed value
in	<i>exp</i>	Regular algebraic expression to prescribe
in	<i>dof</i>	Degree of Freedom for which the value is assigned

**void setNodeBC ( Mesh & *m*, int *code*, const string & *exp* )**

Assign a given function (given by an interpretable algebraic expression) to components of vector with given code.

Vector components are assumed nodewise. Case of 1-DOF problem

Parameters

in	<i>m</i>	Instance of mesh
in	<i>code</i>	Code for which nodes will be assigned prescribed value
in	<i>exp</i>	Regular algebraic expression to prescribe

**void setSideBC ( Mesh & *m*, int *code*, const string & *exp*, size\_t *dof* )**

Assign a given function (given by an interpretable algebraic expression) to components of vector corresponding to sides with given code.

Vector components are assumed nodewise

Parameters

in	<i>m</i>	Instance of mesh
in	<i>code</i>	Code for which nodes will be assigned prescribed value
in	<i>exp</i>	Regular algebraic expression to prescribe
in	<i>dof</i>	Degree of Freedom for which the value is assigned

**void setSideBC ( Mesh & *m*, int *code*, const string & *exp* )**

Assign a given function (given by an interpretable algebraic expression) to components of vector corresponding to sides with given code.

Vector components are assumed nodewise. Case of 1-DOF problem

Parameters

in	<i>m</i>	Instance of mesh
in	<i>code</i>	Code for which nodes will be assigned prescribed value
in	<i>exp</i>	Regular algebraic expression to prescribe

**void setNodeBC ( int *code*, T\_ *val*, size\_t *dof* )**

Assign a given value to components of vector with given code.

Vector components are assumed nodewise

Parameters

in	<i>code</i>	Code for which nodes will be assigned prescribed value
in	<i>val</i>	Value to prescribe
in	<i>dof</i>	Degree of Freedom for which the value is assigned [default: 1]

**void setNodeBC ( int *code*, T\_ *val* )**

Assign a given value to components of vector with given code.

Vector components are assumed nodewise. Concerns 1-DOF problems

Parameters

in	<i>code</i>	Code for which nodes will be assigned prescribed value
in	<i>val</i>	Value to prescribe

**void setNodeBC ( int *code*, const string & *exp*, size\_t *dof* )**

Assign a given function (given by an interpretable algebraic expression) to components of vector with given code.

Vector components are assumed nodewise

Parameters

<code>in</code>	<code>code</code>	Code for which nodes will be assigned prescribed value
<code>in</code>	<code>exp</code>	Regular algebraic expression to prescribe
<code>in</code>	<code>dof</code>	Degree of Freedom for which the value is assigned [default: 1]

Warning

This member function is to be used in the case where a constructor with a [Mesh](#) has been used

**void setNodeBC ( int *code*, const string & *exp* )**

Assign a given function (given by an interpretable algebraic expression) to components of vector with given code.

Vector components are assumed nodewise. Concerns 1-DOF problems

Parameters

<code>in</code>	<code>code</code>	Code for which nodes will be assigned prescribed value
<code>in</code>	<code>exp</code>	Regular algebraic expression to prescribe

Warning

This member function is to be used in the case where a constructor with a [Mesh](#) has been used

**void setSideBC ( int *code*, const string & *exp*, size\_t *dof* )**

Assign a given function (given by an interpretable algebraic expression) to components of vector with given code.

Vector components are assumed nodewise

Parameters

<code>in</code>	<code>code</code>	Code for which nodes will be assigned prescribed value
<code>in</code>	<code>exp</code>	Regular algebraic expression to prescribe
<code>in</code>	<code>dof</code>	Degree of Freedom for which the value is assigned

Warning

This member function is to be used in the case where a constructor with a [Mesh](#) has been used

**void setSideBC ( int *code*, const string & *exp* )**

Assign a given function (given by an interpretable algebraic expression) to components of vector with given code.

Vector components are assumed nodewise. Case of 1-DOF problem

Parameters

<code>in</code>	<code>code</code>	Code for which nodes will be assigned prescribed value
<code>in</code>	<code>exp</code>	Regular algebraic expression to prescribe

Warning

This member function is to be used in the case where a constructor with a [Mesh](#) has been used

**void setSideBC ( int *code*, T\_ *val*, size\_t *dof* )**

Assign a given value to components of vector with given code.

Vector components are assumed nodewise

Parameters

in	<i>code</i>	Code for which nodes will be assigned prescribed value
in	<i>val</i>	Value to prescribe
in	<i>dof</i>	Degree of Freedom for which the value is assigned

Warning

This member function is to be used in the case where a constructor with a [Mesh](#) has been used

**void setSideBC ( int *code*, T\_ *val* )**

Assign a given value to components of vector with given code.

Vector components are assumed nodewise. Concerns 1-DOF problems

Parameters

in	<i>code</i>	Code for which nodes will be assigned prescribed value
in	<i>val</i>	Value to prescribe

Warning

This member function is to be used in the case where a constructor with a [Mesh](#) has been used

**void removeBC ( const Mesh & *ms*, const Vect< T\_ > & *v*, int *dof* = 0 )**

Remove boundary conditions.

This member function copies to current vector a vector where only non imposed DOF are retained.

Parameters

in	<i>ms</i>	<a href="#">Mesh</a> instance
in	<i>v</i>	Vector ( <a href="#">Vect</a> instance to copy from)
in	<i>dof</i>	Parameter to say if all degrees of freedom are concerned (=0, Default) or if only one degree of freedom ( <i>dof</i> ) is inserted into vector <i>v</i> which has only one degree of freedom

**void removeBC ( const Vect< T\_ > & *v*, int *dof* = 0 )**

Remove boundary conditions.

This member function copies to current vector a vector where only non imposed DOF are retained.

Parameters

in	<i>v</i>	Vector ( <a href="#">Vect</a> instance to copy from)
in	<i>dof</i>	Parameter to say if all degrees of freedom are concerned [Default: 0] or if only one degree of freedom ( <i>dof</i> ) is inserted into vector <i>v</i> which has only one degree of freedom.

**Warning**

This member function is to be used in the case where a constructor with a [Mesh](#) has been used

**void transferBC ( const Vect< T\_ > & bc, int dof = 0 )**

Transfer boundary conditions to the vector.

Parameters

in	<i>bc</i>	<a href="#">Vect</a> instance from which imposed degrees of freedom are copied to current instance
in	<i>dof</i>	Parameter to say if all degrees of freedom are concerned (=0, Default) or if only one degree of freedom ( <i>dof</i> ) is inserted into vector <i>v</i> which has only one degree of freedom.

**void insertBC ( Mesh & m, const Vect< T\_ > & v, const Vect< T\_ > & bc, int dof = 0 )**

Insert boundary conditions.

Parameters

in	<i>m</i>	<a href="#">Mesh</a> instance.
in	<i>v</i>	<a href="#">Vect</a> instance from which free degrees of freedom are copied to current instance.
in	<i>bc</i>	<a href="#">Vect</a> instance from which imposed degrees of freedom are copied to current instance.
in	<i>dof</i>	Parameter to say if all degrees of freedom are concerned (=0, Default) or if only one degree of freedom ( <i>dof</i> ) is inserted into vector <i>v</i> which has only one degree of freedom by node or side

**void insertBC ( Mesh & m, const Vect< T\_ > & v, int dof = 0 )**

Insert boundary conditions.

DOF with imposed boundary conditions are set to zero.

Parameters

in	<i>m</i>	<a href="#">Mesh</a> instance.
in	<i>v</i>	<a href="#">Vect</a> instance from which free degrees of freedom are copied to current instance.
in	<i>dof</i>	Parameter to say if all degrees of freedom are concerned (=0, Default) or if only one degree of freedom ( <i>dof</i> ) is inserted into vector <i>v</i> which has only one degree of freedom by node or side

**void insertBC ( const Vect< T\_ > & v, const Vect< T\_ > & bc, int dof = 0 )**

Insert boundary conditions.

## Parameters

in	<i>v</i>	<a href="#">Vect</a> instance from which free degrees of freedom are copied to current instance.
in	<i>bc</i>	<a href="#">Vect</a> instance from which imposed degrees of freedom are copied to current instance.
in	<i>dof</i>	Parameter to say if all degrees of freedom are concerned (=0, Default) or if only one degree of freedom ( <i>dof</i> ) is inserted into vector <i>v</i> which has only one degree of freedom by node or side

**void insertBC ( const Vect< T\_ > & v, int dof = 0 )**

Insert boundary conditions.

DOF with imposed boundary conditions are set to zero.

## Parameters

in	<i>v</i>	<a href="#">Vect</a> instance from which free degrees of freedom are copied to current instance.
in	<i>dof</i>	Parameter to say if all degrees of freedom are concerned (=0, Default) or if only one degree of freedom ( <i>dof</i> ) is inserted into vector <i>v</i> which has only one degree of freedom by node or side

## Warning

This member function is to be used in the case where a constructor with a [Mesh](#) has been used

**void Assembly ( const Element & el, const Vect< T\_ > & b )**

Assembly of element vector into current instance.

## Parameters

in	<i>el</i>	Reference to <a href="#">Element</a> instance
in	<i>b</i>	Local vector to assemble (Instance of class <a href="#">Vect</a> )

**void Assembly ( const Element & el, const T\_ \* b )**

Assembly of element vector (as C-array) into [Vect](#) instance.

## Parameters

in	<i>el</i>	Reference to <a href="#">Element</a> instance
in	<i>b</i>	Local vector to assemble (C-Array)

**void Assembly ( const Side & sd, const Vect< T\_ > & b )**

Assembly of side vector into [Vect](#) instance.

## Parameters

in	<i>sd</i>	Reference to <a href="#">Side</a> instance
in	<i>b</i>	Local vector to assemble (Instance of class <a href="#">Vect</a> )

**void Assembly ( const Side & *sd*, const T\_ \* *b* )**

Assembly of side vector (as C-array) into [Vect](#) instance.

Parameters

<code>in</code>	<code>sd</code>	Reference to <a href="#">Side</a> instance
<code>in</code>	<code>b</code>	Local vector to assemble (C-Array)

**void getGradient ( class Vect< T\_ > & v )**

Evaluate the discrete Gradient vector of the current vector.

The resulting gradient is stored in a [Vect](#) instance. This function handles node vectors assuming  $P_1$  approximation. The gradient is then a constant vector for each element.

Parameters

<code>in</code>	<code>v</code>	<a href="#">Vect</a> instance that contains the gradient, where $v(n,1)$ , $v(n,2)$ and $v(n,3)$ are respectively the x and y and z derivatives at element n.
-----------------	----------------	---

**void getGradient ( Vect< Point< T\_ > > & v )**

Evaluate the discrete Gradient vector of the current vector.

The resulting gradient is stored in an [Vect](#) instance. This function handles node vectors assuming  $P_1$  approximation. The gradient is then a constant vector for each element.

Parameters

<code>in</code>	<code>v</code>	<a href="#">Vect</a> instance that contains the gradient, where $v(n,1).x$ , $v(n,2).y$ and $v(n,3).z$ are respectively the x and y and z derivatives at element n.
-----------------	----------------	---

**void getCurl ( Vect< T\_ > & v )**

Evaluate the discrete curl vector of the current vector.

The resulting curl is stored in a [Vect](#) instance. This function handles node vectors assuming  $P_1$  approximation. The curl is then a constant vector for each element.

Parameters

<code>in</code>	<code>v</code>	<a href="#">Vect</a> instance that contains the curl, where $v(n,1)$ , $v(n,2)$ and $v(n,3)$ are respectively the x and y and z curl components at element n.
-----------------	----------------	---

**void getCurl ( Vect< Point< T\_ > > & v )**

Evaluate the discrete curl vector of the current vector.

The resulting curl is stored in a [Vect](#) instance. This function handles node vectors assuming  $P_1$  approximation. The curl is then a constant vector for each element.

Parameters

<code>in</code>	<code>v</code>	<a href="#">Vect</a> instance that contains the curl, where $v(n,1).x$ , $v(n,2).y$ and $v(n,3).z$ are respectively the x and y and z curl components at element n.
-----------------	----------------	---

**void getSCurl ( Vect< T\_ > & v )**

Evaluate the discrete scalar curl in 2-D of the current vector.

The resulting curl is stored in a [Vect](#) instance. This function handles node vectors assuming  $P_1$  approximation. The curl is then a constant vector for each element.

Parameters

in	<i>v</i>	<a href="#">Vect</a> instance that contains the scalar curl.
----	----------	--

**void getDivergence ( Vect< T\_ > & v )**

Evaluate the discrete Divergence of the current vector.

The resulting divergence is stored in a [Vect](#) instance. This function handles node vectors assuming  $P_1$  approximation. The divergence is then a constant vector for each element.

Parameters

in	<i>v</i>	<a href="#">Vect</a> instance that contains the divergence.
----	----------	---

**real\_t getAverage ( const Element & el, int type ) const**

Return average value of vector in a given element.

Parameters

in	<i>el</i>	<a href="#">Element</a> instance
in	<i>type</i>	Type of element. This is to be chosen among enumerated values: LINE2, TRIANG3, QUAD4, TETRA4, HEXA8, PENTA6

**Vect<T\_>& MultAdd ( const Vect< T\_ > & x, const T\_ & a )**

Multiply by a constant then add to a vector.

Parameters

in	<i>x</i>	<a href="#">Vect</a> instance to add
in	<i>a</i>	Constant to multiply before adding

**void Axpy ( T\_ a, const Vect< T\_ > & x )**

Add to vector the product of a vector by a scalar.

Parameters

in	<i>a</i>	Scalar to premultiply
in	<i>x</i>	<a href="#">Vect</a> instance by which a is multiplied. The result is added to current instance

**void set ( size\_t i, T\_ val )**

Assign a value to an entry for a 1-D vector.

Parameters

in	<i>i</i>	Rank index in vector (starts at 1)
in	<i>val</i>	Value to assign

**void set ( size\_t i, size\_t j, T\_ val )**

Assign a value to an entry for a 2-D vector.

Parameters

<b>in</b>	<i>i</i>	First index in vector (starts at 1)
<b>in</b>	<i>j</i>	Second index in vector (starts at 1)
<b>in</b>	<i>val</i>	Value to assign

**void set ( size\_t i, size\_t j, size\_t k, T\_ val )**

Assign a value to an entry for a 3-D vector.

Parameters

<b>in</b>	<i>i</i>	First index in vector (starts at 1)
<b>in</b>	<i>j</i>	Second index in vector (starts at 1)
<b>in</b>	<i>k</i>	Third index in vector (starts at 1)
<b>in</b>	<i>val</i>	Value to assign

**void add ( size\_t i, T\_ val )**

Add a value to an entry for a 1-index vector.

Parameters

<b>in</b>	<i>i</i>	Rank index in vector (starts at 1)
<b>in</b>	<i>val</i>	Value to assign

**void add ( size\_t i, size\_t j, T\_ val )**

Add a value to an entry for a 2-index vector.

Parameters

<b>in</b>	<i>i</i>	First index in vector (starts at 1)
<b>in</b>	<i>j</i>	Second index in vector (starts at 1)
<b>in</b>	<i>val</i>	Value to assign

**void add ( size\_t i, size\_t j, size\_t k, T\_ val )**

Assign a value to an entry for a 3-index vector.

Parameters

<b>in</b>	<i>i</i>	First index in vector (starts at 1)
<b>in</b>	<i>j</i>	Second index in vector (starts at 1)
<b>in</b>	<i>k</i>	Third index in vector (starts at 1)
<b>in</b>	<i>val</i>	Value to assign

**T\_ & operator() ( size\_t i )**

Operator () (Non constant version)

Parameters

<b>in</b>	<i>i</i>	Rank index in vector (starts at 1) <ul style="list-style-type: none"> <li>• v(i) starts at v(1) to v(size())</li> <li>• v(i) is the same element as v[i-1]</li> </ul>
-----------	----------	---

**T\_ operator() ( size\_t i ) const**

Operator () (Constant version)

Parameters

in	<i>i</i>	Rank index in vector (starts at 1) <ul style="list-style-type: none"> <li>• <code>v(i)</code> starts at <code>v(1)</code> to <code>v(size())</code></li> <li>• <code>v(i)</code> is the same element as <code>v[i-1]</code></li> </ul>
----	----------	--

**T\_& operator() ( size\_t i, size\_t j )**

Operator () with 2-D indexing (Non constant version, case of a grid vector).

Parameters

in	<i>i</i>	first index in vector (Number of vector components in the x-grid)
in	<i>j</i>	second index in vector (Number of vector components in the y-grid) <code>v(i, j)</code> starts at <code>v(1,1)</code> to <code>v(<a href="#">getNx()</a>, <a href="#">getNy()</a>)</code>

**T\_ operator() ( size\_t i, size\_t j ) const**

Operator () with 2-D indexing (Constant version).

Parameters

in	<i>i</i>	first index in vector (Number of vector components in the x-grid)
in	<i>j</i>	second index in vector (Number of vector components in the y-grid) <code>v(i, j)</code> starts at <code>v(1,1)</code> to <code>v(<a href="#">getNx()</a>, <a href="#">getNy()</a>)</code>

**T\_& operator() ( size\_t i, size\_t j, size\_t k )**

Operator () with 3-D indexing (Non constant version).

Parameters

in	<i>i</i>	first index in vector (Number of vector components in the x-grid)
in	<i>j</i>	second index in vector (Number of vector components in the y-grid)
in	<i>k</i>	third index in vector (Number of vector components in the z-grid) <code>v(i, j, k)</code> starts at <code>v(1,1,1)</code> to <code>v(<a href="#">getNx()</a>, <a href="#">getNy()</a>, <a href="#">getNz()</a>)</code>

**T\_ operator() ( size\_t i, size\_t j, size\_t k ) const**

Operator () with 3-D indexing (Constant version).

Parameters

in	<i>i</i>	first index in vector (Number of vector components in the x-grid)
in	<i>j</i>	second index in vector (Number of vector components in the y-grid)
in	<i>k</i>	third index in vector (Number of vector components in the z-grid) <code>v(i, j, k)</code> starts at <code>v(1,1,1)</code> to <code>v(<a href="#">getNx()</a>, <a href="#">getNy()</a>, <a href="#">getNz()</a>)</code>

**T\_& operator() ( size\_t *i*, size\_t *j*, size\_t *k*, size\_t *l* )**

Operator () with 4-D indexing (Non constant version).

Parameters

in	<i>i</i>	first index in vector (Number of vector components in the x-grid)
in	<i>j</i>	second index in vector (Number of vector components in the y-grid)
in	<i>k</i>	third index in vector (Number of vector components in the z-grid)
in	<i>l</i>	fourth index in vector (Number of vector components in the t-grid) $v(i,j,k,l)$ starts at $v(1,1,1,1)$ to $v(\text{getNx}(), \text{getNy}(), \text{getNz}(), \text{getNt}())$

**T\_ operator() ( size\_t i, size\_t j, size\_t k, size\_t l ) const**

Operator () with 4-D indexing (Constant version).

Parameters

in	<i>i</i>	first index in vector (Number of vector components in the x-grid)
in	<i>j</i>	second index in vector (Number of vector components in the y-grid)
in	<i>k</i>	third index in vector (Number of vector components in the z-grid)
in	<i>l</i>	third index in vector (Number of vector components in the t-grid) $v(i,j,k,l)$ starts at $v(1,1,1,1)$ to $v(\text{getNx}(), \text{getNy}(), \text{getNz}(), \text{getNt}())$

**void operator= ( string s )**

Operator =

Assign an algebraic expression to vector entries. This operator has the same effect as the member function set(s)

Parameters

in	<i>s</i>	String defining the algebraic expression as a function of coordinates and time
----	----------	--

Warning

A [Mesh](#) instance must has been introduced before (e.g. by a constructor)**void setUniform ( T\_ vmin, T\_ vmax, size\_t n )**

Initialize vector entries by setting extremal values and interval.

Parameters

in	<i>vmin</i>	Minimal value to assign to the first entry
in	<i>vmax</i>	Maximal value to assign to the lase entry
in	<i>n</i>	Number of points (including extremities)

Remarks

The vector has a size of n. It is sized in this function

**Vect<T\_>& operator= ( const T\_ & a )**

Operator =

Assign a constant to vector entries

Parameters

in	<i>a</i>	Value to set
----	----------	--------------

**Vect<T\_>& operator+= ( const Vect< T\_ > & *v* )**

Operator +=

Add vector *x* to current vector instance.

Parameters

in	<i>v</i>	<a href="#">Vect</a> instance to add to instance
----	----------	--

**Vect<T\_>& operator+= ( const T\_ & *a* )**

Operator +=

Add a constant to current vector entries.

Parameters

in	<i>a</i>	Value to add to vector entries
----	----------	--------------------------------

**Vect<T\_>& operator-= ( const Vect< T\_ > & *v* )**

Operator -=

Parameters

in	<i>v</i>	<a href="#">Vect</a> instance to subtract from
----	----------	--

**Vect<T\_>& operator-= ( const T\_ & *a* )**

Operator -=

Subtract constant from vector entries.

Parameters

in	<i>a</i>	Value to subtract from
----	----------	------------------------

**Vect<T\_>& operator\*= ( const T\_ & *a* )**

Operator \*=

Parameters

in	<i>a</i>	Value to multiply by
----	----------	----------------------

**Vect<T\_>& operator/= ( const T\_ & *a* )**

Operator /=

Parameters

in	<i>a</i>	Value to divide by
----	----------	--------------------

**void push\_back ( const T\_ & *v* )**

Add an entry to the vector.

This function is an overload of the member function push\_back of the parent class vector. It adjusts in addition some vector parameters

Parameters

in	<i>v</i>	Entry value to add
----	----------	--------------------

**T\_ operator, ( const Vect< T\_ > & *v* ) const**

Return Dot (scalar) product of two vectors.

A typical use of this operator is `double a = (v,w)` where *v* and *w* are 2 instances of `Vect<double>`

Parameters

in	<i>v</i>	<a href="#">Vect</a> instance by which the current instance is multiplied
----	----------	---

**Vect<complex.t> getFFT ( )**

Compute FFT transform of vector.

This member function computes the FFT (Fast Fourier Transform) of the vector contained in the instance and returns it

Returns

[Vect<complex<double> >](#) instance containing the FFT

Remarks

The size of [Vect](#) instance must be a power of two and must not exceed the value of `2^MAX_X_FFT_SIZE` (This value is set in the header "constants.h")

The [Vect](#) instance can be either a `Vect<double>` or `Vec<complex<double> >`

**Vect<complex.t> getInvFFT ( )**

Compute Inverse FFT transform of vector.

This member function computes the inverse FFT (Fast Fourier Transform) of the vector contained in the instance and returns it

Returns

[Vect<complex<double> >](#) instance containing the FFT

Remarks

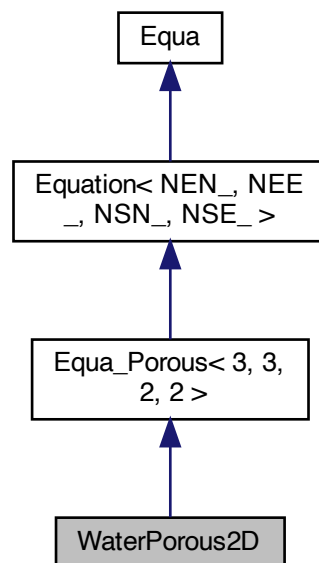

The size of [Vect](#) instance must be a power of two and must not exceed the value of `2^MAX_X_FFT_SIZE` (This value is set in the header "constants.h")

The [Vect](#) instance can be either a `Vect<double>` or `Vec<complex<double> >`

### 7.116.1 Detailed Description

To solve water flow equations in porous media (1-D)

To solve water flow equations in porous media (2-D)

Class [WaterPorous2D](#) solves the fluid flow equations of water or any incompressible or slightly compressible fluid in a porous medium in two-dimensional configurations.

Porous media flows are modelled here by the Darcy law. The water, or any other fluid is considered as slightly compressible, i.e., its compressibility coefficient is constant.

Space discretization uses the  $P_1$  (2-Node line) finite element method. Time integration uses class [TimeStepping](#) that provides various well known time integration schemes.

Class [WaterPorous2D](#) solves the fluid flow equations of water or any incompressible or slightly compressible fluid in a porous medium in two-dimensional configurations.

Porous media flows are modelled here by the Darcy law. The water, or any other fluid is considered as slightly compressible, i.e., its compressibility coefficient is constant.

Space discretization uses the  $P_1$  (3-Node triangle) finite element method. Time integration uses class [TimeStepping](#) that provides various well known time integration schemes.

## 7.116.2 Constructor & Destructor Documentation

### **WaterPorous2D ( )**

Default Constructor.

Constructs an empty equation.

### **WaterPorous2D ( Mesh & ms )**

Constructor.

This constructor uses mesh and reservoir information

Parameters

in	ms	<a href="#">Mesh</a> instance
----	----	-------------------------------

## 7.116.3 Member Function Documentation

### **void setCoef ( real\_t cw, real\_t phi, real\_t rho, real\_t Kx, real\_t Ky, real\_t mu )**

Set constant coefficients.

Parameters

in	cw	Compressibility coefficient
in	phi	Porosity
in	rho	Density
in	Kx	x-Absolute permeability
in	Ky	y-Absolute permeability
in	mu	Viscosity

### **void BodyRHS ( const Vect< real\_t > & bf ) [virtual]**

Add source right-hand side term to right-hand side.

Parameters

in	bf	Vector containing source at nodes.
----	----	------------------------------------

Reimplemented from [Equa.Porous< 3, 3, 2, 2 >](#).

### **void BoundaryRHS ( const Vect< real\_t > & sf ) [virtual]**

Add boundary right-hand side term to right-hand side.

## Parameters

<code>in</code>	<code>sf</code>	Vector containing source at nodes.
-----------------	-----------------	------------------------------------

Reimplemented from [Equa.Porous< 3, 3, 2, 2 >](#).
